INTRODUCTION

In the previous chapters, we have discussed the circuit applications of an ordinary transistor. In this type of transistor, both holes and electrons play part in the conduction process. For this reason, it is sometimes called a bipolar transistor. The ordinary or bipolar transistor has two principal disadvantages. First, it has a low input impedance because of forward biased emitter junction. Secondly, it has considerable noise level. Although low input impedance problem may be improved by careful design and use of more than one transistor, yet it is difficult to achieve input impedance more than a few megaohms. The field effect transistor (FET) has, by virtue of its construction and biasing, large input impedance which may be more than 100 megaohms. The FET is generally much less noisy than the ordinary or bipolar transistor. The rapidly expanding FET market has led many semiconductor market-
ing managers to believe that this device will soon become the most important electronic device, primarily because of its integrated-circuit applications. In this chapter, we shall focus our attention on the construction, working and circuit applications of field effect transistors.

19.1 Types of Field Effect Transistors

A bipolar junction transistor (BJT) is a current controlled device i.e., output characteristics of the device are controlled by base current and not by base voltage. However, in a field effect transistor (FET), the output characteristics are controlled by input voltage (i.e., electric field) and not by input current. This is probably the biggest difference between BJT and FET. There are two basic types of field effect transistors:

(i) Junction field effect transistor (JFET)
(ii) Metal oxide semiconductor field effect transistor (MOSFET)

To begin with, we shall study about JFET and then improved form of JFET, namely; MOSFET.

19.2 Junction Field Effect Transistor (JFET)

A junction field effect transistor is a three terminal semiconductor device in which current conduction is by one type of carrier i.e., electrons or holes.

The JFET was developed about the same time as the transistor but it came into general use only in the late 1960s. In a JFET, the current conduction is either by electrons or holes and is controlled by means of an electric field between the gate electrode and the conducting channel of the device. The JFET has high input impedance and low noise level.

Constructional details. A JFET consists of a p-type or n-type silicon bar containing two pn junctions at the sides as shown in Fig.19.1. The bar forms the conducting channel for the charge carriers. If the bar is of n-type, it is called n-channel JFET as shown in Fig. 19.1 (i) and if the bar is of p-type, it is called a p-channel JFET as shown in Fig. 19.1 (ii). The two pn junctions forming diodes are connected *internally and a common terminal called gate is taken out. Other terminals are source and drain taken out from the bar as shown. Thus a JFET has essentially three terminals viz., gate (G), source (S) and drain (D).

![Fig. 19.1](image)

* It would seem from Fig. 19.1 that there are three doped material regions. However, this is not the case. The gate material surrounds the channel in the same manner as a belt surrounding your waist.
**JFET polarities.** Fig. 19.2 (i) shows n-channel JFET polarities whereas Fig. 19.2 (ii) shows the p-channel JFET polarities. Note that in each case, the voltage between the gate and source is such that the gate is reverse biased. This is the normal way of JFET connection. The drain and source terminals are interchangeable i.e., either end can be used as source and the other end as drain.

The following points may be noted:

(i) The input circuit (i.e. gate to source) of a JFET is reverse biased. This means that the device has high input impedance.

(ii) The drain is so biased w.r.t. source that drain current $I_D$ flows from the source to drain.

(iii) In all JFETs, source current $I_S$ is equal to the drain current i.e. $I_S = I_D$.

### 19.3 Principle and Working of JFET

Fig. 19.3 shows the circuit of n-channel JFET with normal polarities. Note that the gate is reverse biased.

**Principle.** The two pn junctions at the sides form two depletion layers. The current conduction by charge carriers (i.e. free electrons in this case) is through the channel between the two depletion layers and out of the drain. The width and hence resistance of this channel can be controlled by changing the input voltage $V_{GS}$. The greater the reverse voltage $V_{GS}$, the wider will be the depletion layers and narrower will be the conducting channel. The narrower channel means greater resistance and hence source to drain current decreases. Reverse will happen should $V_{GS}$ decrease. Thus JFET operates on the principle that width and hence resistance of the conducting channel can be varied by changing the reverse voltage $V_{GS}$. In other words, the magnitude of drain current ($I_D$) can be changed by altering $V_{GS}$.

**Working.** The working of JFET is as under:

(i) When a voltage $V_{DS}$ is applied between drain and source terminals and voltage on the gate is zero [See Fig. 19.3 (i)], the two pn junctions at the sides of the bar establish depletion layers. The electrons will flow from source to drain through a channel between the depletion layers. The size of these layers determines the width of the channel and hence the current conduction through the bar.

(ii) When a reverse voltage $V_{GS}$ is applied between the gate and source [See Fig. 19.3 (ii)], the width of the depletion layers is increased. This reduces the width of conducting channel, thereby increasing the resistance of n-type bar. Consequently, the current from source to drain is decreased. On the other hand, if the reverse voltage on the gate is decreased, the width of the depletion layers also decreases. This increases the width of the conducting channel and hence source to drain current.

* The resistance of the channel depends upon its area of X-section. The greater the X-sectional area of this channel, the lower will be its resistance and the greater will be the current flow through it.
It is clear from the above discussion that current from source to drain can be controlled by the application of potential (i.e. electric field) on the gate. For this reason, the device is called field effect transistor. It may be noted that a p-channel JFET operates in the same manner as an n-channel JFET except that channel current carriers will be the holes instead of electrons and the polarities of $V_{GS}$ and $V_{DS}$ are reversed.

**Note.** If the reverse voltage $V_{GS}$ on the gate is continuously increased, a state is reached when the two depletion layers touch each other and the channel is cut off. Under such conditions, the channel becomes a non-conductor.

### 19.4 Schematic Symbol of JFET

Fig. 19.4 shows the schematic symbol of JFET. The vertical line in the symbol may be thought
as channel and source (S) and drain (D) connected to this line. If the channel is \( n \)-type, the arrow on the gate points towards the channel as shown in Fig. 19.4 (i). However, for \( p \)-type channel, the arrow on the gate points from channel to gate [See Fig. 19.4 (ii)].

19.5 Importance of JFET

A JFET acts like a voltage controlled device i.e. input voltage \( V_{GS} \) controls the output current. This is different from ordinary transistor (or bipolar transistor) where input current controls the output current. Thus JFET is a semiconductor device acting \*like a vacuum tube. The need for JFET arose because as modern electronic equipment became increasingly transistorised, it became apparent that there were many functions in which bipolar transistors were unable to replace vacuum tubes. Owing to their extremely high input impedance, JFET devices are more like vacuum tubes than are the bipolar transistors and hence are able to take over many vacuum-tube functions. Thus, because of JFET, electronic equipment is closer today to being completely solid state.

The JFET devices have not only taken over the functions of vacuum tubes but they now also threaten to depose the bipolar transistors as the most widely used semiconductor devices. As an amplifier, the JFET has higher input impedance than that of a conventional transistor, generates less noise and has greater resistance to nuclear radiations.

19.6 Difference Between JFET and Bipolar Transistor

The JFET differs from an ordinary or bipolar transistor in the following ways:

(i) In a JFET, there is only one type of carrier, holes in \( p \)-type channel and electrons in \( n \)-type channel. For this reason, it is also called a unipolar transistor. However, in an ordinary transistor, both holes and electrons play part in conduction. Therefore, an ordinary transistor is sometimes called a bipolar transistor.

(ii) As the input circuit (i.e., gate to source) of a JFET is reverse biased, therefore, the device has high input impedance. However, the input circuit of an ordinary transistor is forward biased and hence has low input impedance.

(iii) The primary functional difference between the JFET and the BJT is that no current (actually, a very, very small current) enters the gate of JFET (i.e. \( I_G = 0 \)A). However, typical BJT base current might be a few \( \mu \)A while JFET gate current a thousand times smaller [See Fig. 19.5].

* The gate, source and drain of a JFET correspond to grid, cathode and anode of a vacuum tube.
Field Effect Transistors

\[ (iv) \] A bipolar transistor uses a current into its base to control a large current between collector and emitter whereas a \textit{JFET} uses voltage on the ‘gate’ (=base) terminal to control the current between drain (= collector) and source (= emitter). Thus a bipolar transistor gain is characterised by current gain whereas the \textit{JFET} gain is characterised as a transconductance \( i.e., \) the ratio of change in output current (drain current) to the input (gate) voltage.

\[ (v) \] In \textit{JFET}, there are no junctions as in an ordinary transistor. The conduction is through an \( n \)-type or \( p \)-type semi-conductor material. For this reason, noise level in \textit{JFET} is very small.

### 19.7 \textit{JFET} as an Amplifier

Fig. 19.6 shows \textit{JFET} amplifier circuit. The weak signal is applied between gate and source and amplified output is obtained in the drain-source circuit. For the proper operation of \textit{JFET}, the gate must be negative w.r.t. source \( i.e., \) input circuit should always be reverse biased. This is achieved either by inserting a battery \( V_{GG} \) in the gate circuit or by a circuit known as biasing circuit. In the present case, we are providing biasing by the battery \( V_{GG} \).

A small change in the reverse bias on the gate produces a large change in drain current. This fact makes \textit{JFET} capable of raising the strength of a weak signal. During the positive half of signal, the reverse bias on the gate decreases. This increases the channel width and hence the drain current. During the negative half-cycle of the signal, the reverse voltage on the gate increases. Consequently, the drain current decreases. The result is that a small change in voltage at the gate produces a large change in drain current. These large variations in drain current produce large output across the load \( R_L \). In this way, \textit{JFET} acts as an amplifier.

### 19.8 Output Characteristics of \textit{JFET}

The curve between drain current \( (I_D) \) and drain-source voltage \( (V_{DS}) \) of a \textit{JFET} at constant gate-source voltage \( (V_{GS}) \) is known as \textit{output characteristics of \textit{JFET}}. Fig. 19.7 shows the circuit for determining the output characteristics of \textit{JFET}. Keeping \( V_{GS} \) fixed at some value, say 1V, the drain-source voltage is changed in steps. Corresponding to each value of \( V_{DS} \), the drain current \( I_D \) is noted. A plot of these values gives the output characteristic of \textit{JFET} at \( V_{GS} = 1 \text{V} \). Repeating similar procedure, output characteristics at other gate-source voltages can be drawn. Fig. 19.8 shows a family of output characteristics.
The following points may be noted from the characteristics:

(i) At first, the drain current $I_D$ rises rapidly with drain-source voltage $V_{DS}$ but then becomes constant. The drain-source voltage above which drain current becomes constant is known as pinch off voltage. Thus in Fig. 19.8, $OA$ is the pinch off voltage $V_P$.

(ii) After pinch off voltage, the channel width becomes so narrow that depletion layers almost touch each other. The drain current passes through the small passage between these layers. Therefore, increase in drain current is very small with $V_{DS}$ above pinch off voltage. Consequently, drain current remains constant.

(iii) The characteristics resemble that of a pentode valve.

19.9 Salient Features of JFET

The following are some salient features of JFET:

(i) A JFET is a three-terminal voltage-controlled semiconductor device i.e. input voltage controls the output characteristics of JFET.

(ii) The JFET is always operated with gate-source $pn$ junction reverse biased.

(iii) In a JFET, the gate current is zero i.e. $I_G = 0A$.

(iv) Since there is no gate current, $I_D = I_S$.

(v) The JFET must be operated between $V_{GS}$ and $V_{GS(off)}$. For this range of gate-to-source voltages, $I_D$ will vary from a maximum of $I_{DSS}$ to a minimum of almost zero.

(vi) Because the two gates are at the same potential, both depletion layers widen or narrow down by an equal amount.

(vii) The JFET is not subjected to thermal runaway when the temperature of the device increases.

(viii) The drain current $I_D$ is controlled by changing the channel width.

(ix) Since JFET has no gate current, there is no $\beta$ rating of the device. We can find drain current $I_D$ by using the eq. mentioned in Art. 19.11.

19.10 Important Terms

In the analysis of a JFET circuit, the following important terms are often used:

1. Shorted-gate drain current ($I_{DSS}$)
2. Pinch off voltage ($V_P$)
3. Gate-source cut off voltage [$V_{GS(off)}$]

1. Shorted-gate drain current ($I_{DSS}$). It is the drain current with source short-circuited to gate (i.e. $V_{GS} = 0$) and drain voltage ($V_{DS}$) equal to pinch off voltage. It is sometimes called zero-bias current.

Fig 19.9 shows the JFET circuit with $V_{GS} = 0$ i.e., source short-circuited to gate. This is normally called shorted-gate condition. Fig. 19.10 shows the graph between $I_D$ and $V_{DS}$ for the shorted gate condition. The drain current rises rapidly at first and then levels off at pinch off voltage $V_P$. The drain current has now reached the maximum value $I_{DSS}$. When $V_{DS}$ is increased beyond $V_P$, the depletion layers expand at the top of the channel. The channel now acts as a current limiter and holds drain current at a constant value of $I_{DSS}$.

* Forward biasing gate-source $pn$ junction may destroy the device.

** When drain voltage equals $V_P$, the channel becomes narrow and the depletion layers almost touch each other. The channel now acts as a current limiter and holds drain current at a constant value of $I_{DSS}$. 
The following points may be noted carefully:

(i) Since $I_{DSS}$ is measured under shorted gate conditions, it is the maximum drain current that you can get with normal operation of JFET.

(ii) There is a maximum drain voltage $[V_{DS(max)}]$ that can be applied to a JFET. If the drain voltage exceeds $V_{DS(max)}$, JFET would breakdown as shown in Fig. 19.10.

(iii) The region between $V_P$ and $V_{DS(max)}$ (breakdown voltage) is called constant-current region or active region. As long as $V_{DS}$ is kept within this range, $I_D$ will remain constant for a constant value of $V_{GS}$. In other words, in the active region, JFET behaves as a constant–current device. For proper working of JFET, it must be operated in the active region.

2. Pinch off Voltage ($V_P$). It is the minimum drain-source voltage at which the drain current essentially becomes constant.

Figure 19.11 shows the drain curves of a JFET. Note that pinch off voltage is $V_P$. The highest curve is for $V_{GS} = 0V$, the shorted-gate condition. For values of $V_{DS}$ greater than $V_P$, the drain current is almost constant. It is because when $V_{DS}$ equals $V_P$, the channel is effectively closed and does not allow further increase in drain current. It may be noted that for proper function of JFET, it is always operated for $V_{DS} > V_P$. However, $V_{DS}$ should not exceed $V_{DS(max)}$ otherwise JFET may breakdown.
3. Gate-source cut off voltage $V_{GS\,(off)}$. It is the gate-source voltage where the channel is completely cut off and the drain current becomes zero.

The idea of gate-source cut off voltage can be easily understood if we refer to the transfer characteristic of a JFET shown in Fig. 19.12. As the reverse gate-source voltage is increased, the cross-sectional area of the channel decreases. This in turn decreases the drain current. At some reverse gate-source voltage, the depletion layers extend completely across the channel. In this condition, the channel is cut off and the drain current reduces to zero. The gate voltage at which the channel is cut off (i.e. channel becomes non-conducting) is called gate-source cut off voltage $V_{GS\,(off)}$.

Notes. (i) It is interesting to note that $V_{GS\,(off)}$ will always have the same magnitude value as $V_P$. For example if $V_P = 6$ V, then $V_{GS\,(off)} = -6$ V. Since these two values are always equal and opposite, only one is listed on the specification sheet for a given JFET.

(ii) There is a distinct difference between $V_P$ and $V_{GS\,(off)}$. Note that $V_P$ is the value of $V_{DS}$ that causes the JFET to become a constant current device. It is measured at $V_{GS} = 0$ V and will have a constant drain current = $I_{DSS}$. However, $V_{GS\,(off)}$ is the value of $V_{GS}$ that causes $I_D$ to drop to nearly zero.

19.11 Expression for Drain Current ($I_D$)

The relation between $I_{DSS}$ and $V_P$ is shown in Fig. 19.13. We note that gate-source cut off voltage [i.e. $V_{GS\,(off)}$] on the transfer characteristic is equal to pinch off voltage $V_P$ on the drain characteristic i.e.

$$V_P = |V_{GS\,(off)}|$$

For example, if a JFET has $V_{GS\,(off)} = -4$ V, then $V_P = 4$ V.

The transfer characteristic of JFET shown in Fig. 19.13 is part of a parabola. A rather complex mathematical analysis yields the following expression for drain current:

$$I_D = I_{DSS} \left[1 - \frac{V_{GS}}{V_{GS\,(off)}} \right]^2$$

where

- $I_D$ = drain current at given $V_{GS}$
- $I_{DSS}$ = shorted – gate drain current
- $V_{GS}$ = gate–source voltage
- $V_{GS\,(off)}$ = gate–source cut off voltage

![Fig. 19.13](image-url)
Example 19.1. Fig. 19.14 shows the transfer characteristic curve of a JFET. Write the equation for drain current.

Solution. Referring to the transfer characteristic curve in Fig. 19.14, we have,

\[ I_{DSS} = 12 \text{ mA} \]
\[ V_{GS\,(off)} = -5 \text{ V} \]

\[ I_D = I_{DSS} \left[ 1 - \frac{V_{GS}}{V_{GS\,(off)}} \right]^2 \]

or

\[ I_D = 12 \left[ 1 + \frac{V_{GS}}{5} \right]^2 \text{ mA} \quad \text{Ans.} \]

Example 19.2. A JFET has the following parameters: \( I_{DSS} = 32 \text{ mA} \); \( V_{GS\,(off)} = -8 \text{ V} \); \( V_{GS} = -4.5 \text{ V} \). Find the value of drain current.

Solution.

\[ I_D = I_{DSS} \left[ 1 - \frac{V_{GS}}{V_{GS\,(off)}} \right]^2 \]

\[ = 32 \left[ 1 - \frac{(-4.5)}{-8} \right]^2 \text{ mA} \]

\[ = 6.12 \text{ mA} \]

Example 19.3. A JFET has a drain current of 5 mA. If \( I_{DSS} = 10 \text{ mA} \) and \( V_{GS\,(off)} = -6 \text{ V} \), find the value of (i) \( V_{GS} \) and (ii) \( V_P \).

Solution.

\[ I_D = I_{DSS} \left[ 1 - \frac{V_{GS}}{V_{GS\,(off)}} \right]^2 \]

or

\[ 5 = 10 \left[ 1 + \frac{V_{GS}}{6} \right]^2 \]

or

\[ 1 + \frac{V_{GS}}{6} = \sqrt{5/10} = 0.707 \]

(i) \[ V_{GS} = -1.76 \text{ V} \]

(ii) and \[ V_P = -V_{GS\,(off)} = 6 \text{ V} \]

Example 19.4. For the JFET in Fig. 19.15, \( V_{GS\,(off)} = -4 \text{ V} \) and \( I_{DSS} = 12 \text{ mA} \). Determine the minimum value of \( V_{DD} \) required to put the device in the constant-current region of operation.

Solution. Since \( V_{GS\,(off)} = -4 \text{ V} \), \( V_P = 4 \text{ V} \). The minimum value of \( V_{DS} \) for the JFET to be in constant-current region is

\[ V_{DS} = V_P = 4 \text{ V} \]

In the constant current region with \( V_{GS} = 0 \text{ V} \),

\[ I_D = I_{DSS} = 12 \text{ mA} \]

Applying Kirchhoff’s voltage law around the drain circuit, we have,

\[ V_{DD} = V_{DS} + V_{R_P} = V_{DS} + I_D R_D \]

\[ = 4V + (12 \text{ mA}) (560\Omega) = 4V + 6.72V = 10.72V \]

This is the value of \( V_{DD} \) to make \( V_{DS} = V_P \) and put the device in the constant-current region.
Example 19.5. Determine the value of drain current for the circuit shown in Fig. 19.16.

Solution. It is clear from Fig. 19.16 that $V_{GS} = -2V$. The drain current for the circuit is given by;

$$I_D = I_{DSS} \left(1 - \frac{V_{GS}}{V_{GS\ (off)}}\right)^2$$

$$= 3\ mA \left(1 - \frac{-2V}{6V}\right)^2$$

$$= (3\ mA) (0.444) = 1.33\ mA$$

Example 19.6. A particular p-channel JFET has a $V_{GS\ (off)} = +4V$. What is $I_D$ when $V_{GS} = +6V$?

Solution. The p-channel JFET requires a positive gate-to-source voltage to pass drain current $I_D$. The more the positive voltage, the less the drain current. When $V_{GS} = 4V$, $I_D = 0$ and JFET is cut off. Any further increase in $V_{GS}$ keeps the JFET cut off. Therefore, at $V_{GS} = +6V$, $I_D = 0A$.

19.12 Advantages of JFET

A JFET is a voltage controlled, constant current device (similar to a vacuum pentode) in which variations in input voltage control the output current. It combines the many advantages of both bipolar transistor and vacuum pentode. Some of the advantages of a JFET are:

(i) It has a very high input impedance (of the order of 100 MΩ). This permits high degree of isolation between the input and output circuits.

(ii) The operation of a JFET depends upon the bulk material current carriers that do not cross junctions. Therefore, the inherent noise of tubes (due to high-temperature operation) and those of transistors (due to junction transitions) are not present in a JFET.

(iii) A JFET has a negative temperature coefficient of resistance. This avoids the risk of thermal runaway.

(iv) A JFET has a very high power gain. This eliminates the necessity of using driver stages.

(v) A JFET has a smaller size, longer life and high efficiency.

19.13 Parameters of JFET

Like vacuum tubes, a JFET has certain parameters which determine its performance in a circuit. The main parameters of a JFET are (i) a.c. drain resistance (ii) transconductance (iii) amplification factor.

(i) a.c. drain resistance ($r_d$). Corresponding to the a.c. plate resistance, we have a.c. drain resistance in a JFET. It may be defined as follows:
Field Effect Transistors

It is the ratio of change in drain-source voltage (ΔV_{DS}) to the change in drain current (ΔI_D) at constant gate-source voltage i.e.

\[ r_d = \frac{\Delta V_{DS}}{\Delta I_D} \text{ at constant } V_{GS} \]

For instance, if a change in drain voltage of 2 V produces a change in drain current of 0.02 mA, then,

\[ r_d = \frac{2 \text{ V}}{0.02 \text{ mA}} = 100 \text{ kΩ} \]

Referring to the output characteristics of a JFET in Fig. 19.8, it is clear that above the pinchoff voltage, the change in \( I_D \) is small for a change in \( V_{DS} \) because the curve is almost flat. Therefore, drain resistance of a JFET has a large value, ranging from 10 kΩ to 1 MΩ.

(ii) Transconductance (\( g_{fs} \)). The control that the gate voltage has over the drain current is measured by transconductance \( g_{fs} \) and is similar to the transconductance \( g_m \) of the tube. It may be defined as follows:

\[ g_{fs} = \frac{\Delta I_D}{\Delta V_{GS}} \text{ at constant } V_{DS} \]

The transconductance of a JFET is usually expressed either in mA/volt or micromho. As an example, if a change in gate voltage of 0.1 V causes a change in drain current of 0.3 mA, then,

\[ g_{fs} = \frac{0.3 \text{ mA}}{0.1 \text{ V}} = 3 \text{ mA/V} = 3 \times 10^{-3} \text{ A/V or mho or S (siemens)} \]

\[ = 3 \times 10^{-3} \times 10^6 \text{ µmho} = 3000 \text{ µmho (or } \mu \text{S)} \]

(iii) Amplification factor (\( µ \)). It is the ratio of change in drain-source voltage (ΔV_{DS}) to the change in gate-source voltage (ΔV_{GS}) at constant drain current i.e.

\[ µ = \frac{\Delta V_{DS}}{\Delta V_{GS}} \text{ at constant } I_D \]

Amplification factor of a JFET indicates how much more control the gate voltage has over drain current than has the drain voltage. For instance, if the amplification factor of a JFET is 50, it means that gate voltage is 50 times as effective as the drain voltage in controlling the drain current.

19.14 Relation Among JFET Parameters

The relationship among JFET parameters can be established as under:

We know

\[ µ = \frac{\Delta V_{DS}}{\Delta V_{GS}} \]

Multiplying the numerator and denominator on R.H.S. by \( \Delta I_D \), we get,

\[ µ = \frac{\Delta V_{DS} \times \Delta I_D}{\Delta V_{GS} \times \Delta I_D} = \frac{\Delta V_{DS}}{\Delta V_{GS}} \frac{\Delta I_D}{\Delta I_D} \]

\[ ∴ \quad \mu = r_d \times g_{fs} \]

i.e.

amplification factor = a.c. drain resistance \( \times \) transconductance

Example 19.7. When a reverse gate voltage of 15 V is applied to a JFET, the gate current is \( 10^{-3} \mu \text{A} \). Find the resistance between gate and source.

Solution.\[ V_{GS} = 15 \text{ V} \; ; \; I_G = 10^{-3} \mu \text{A} = 10^{-9} \text{ A} \]
Gate to source resistance \( \frac{V_{GS}}{I_G} = \frac{15 \text{ V}}{10^{-3} \text{ A}} = 15 \times 10^9 \Omega = 15,000 \text{ M}\Omega \)

This example shows the major difference between a JFET and a bipolar transistor. Whereas the input impedance of a JFET is several hundred M\(\Omega\), the input impedance of a bipolar transistor is only hundreds or thousands of ohms. The large input impedance of a JFET permits high degree of isolation between the input and output.

**Example 19.8.** When \( V_{GS} \) of a JFET changes from \(-3.1 \text{ V}\) to \(-3 \text{ V}\), the drain current changes from 1 mA to 1.3 mA. What is the value of transconductance ?

**Solution.**

\[
\begin{align*}
\Delta V_{GS} &= 3.1 - 3 = 0.1 \text{ V} \quad \ldots \text{ magnitude} \\
\Delta I_D &= 1.3 - 1 = 0.3 \text{ mA}
\end{align*}
\]

\[ g_{fs} = \frac{\Delta I_D}{\Delta V_{GS}} = \frac{0.3 \text{ mA}}{0.1 \text{ V}} = 3 \text{ mA/V} = 3000 \mu\text{mho} \]

**Example 19.9.** The following readings were obtained experimentally from a JFET:

</table>

Determine (i) a. c. drain resistance (ii) transconductance and (iii) amplification factor.

**Solution.**

(i) With \( V_{GS} \) constant at 0V, the increase in \( V_{DS} \) from 7 V to 15 V increases the drain current from 10 mA to 10.25 mA i.e.

\[
\Delta V_{DS} = 15 - 7 = 8 \text{ V} \\
\Delta I_D = 10.25 - 10 = 0.25 \text{ mA}
\]

\[ r_d = \frac{\Delta V_{DS}}{\Delta I_D} = \frac{8 \text{ V}}{0.25 \text{ mA}} = 32 \text{ k}\Omega \]

(ii) With \( V_{DS} \) constant at 15 V, drain current changes from 10.25 mA to 9.65 mA as \( V_{GS} \) is changed from 0 V to –0.2 V.

\[ \Delta V_{GS} = 0.2 - 0 = 0.2 \text{ V} \]

\[ \Delta I_D = 10.25 - 9.65 = 0.6 \text{ mA} \]

\[ g_{fs} = \frac{\Delta I_D}{\Delta V_{GS}} = \frac{0.6 \text{ mA}}{0.2 \text{ V}} = 3 \text{ mA/V} = 3000 \mu\text{mho} \]

(iii) Amplification factor, \( \mu = r_d \times g_{fs} = (32 \times 10^3) \times (3000 \times 10^{-6}) = 96 \)

**19.15 Variation of Transconductance (\( g_m \) or \( g_{fs} \)) of JFET**

We have seen that transconductance \( g_m \) of a JFET is the ratio of a change in drain current (\( \Delta I_D \)) to a change in gate-source voltage (\( \Delta V_{GS} \)) at constant \( V_{DS} \) i.e.

\[ g_m = \frac{\Delta I_D}{\Delta V_{GS}} \]

The transconductance \( g_m \) of a JFET is an important parameter because it is a major factor in determining the voltage gain of JFET amplifiers. However, the transfer characteristic curve for a JFET is nonlinear so that the value of \( g_m \) depends upon the location on the curve. Thus the value of \( g_m \) at point A in Fig. 19.17 will be different from that at point B. Luckily, there is following equation to determine the value of \( g_m \) at a specified value of \( V_{GS} \).

![Fig. 19.17](image-url)
Field Effect Transistors

\[ g_m = g_{mo} \left( 1 - \frac{V_{GS}}{V_{GS\,(off)}} \right) \]

where \( g_m \) = value of transconductance at any point on the transfer characteristic curve
\( g_{mo} \) = value of transconductance(maximum) at \( V_{GS} = 0 \)

Normally, the data sheet provides the value of \( g_{mo} \). When the value of \( g_{mo} \) is not available, you can approximately calculate \( g_{mo} \) using the following relation:

\[ g_{mo} = \frac{2I_{DSS}}{|V_{GS\,(off)}|} \]

**Example 19.10.** A JFET has a value of \( g_{mo} = 4000 \, \mu S \). Determine the value of \( g_m \) at \( V_{GS} = -3V \). Given that \( V_{GS\,(off)} = -8V \).

**Solution.**

\[ g_m = g_{mo} \left( 1 - \frac{V_{GS}}{V_{GS\,(off)}} \right) \]
\[ = 4000 \, \mu S \left( 1 - \frac{-3V}{-8V} \right) \]
\[ = 4000 \, \mu S (0.625) = 2500 \, \mu S \]

**Example 19.11.** The data sheet of a JFET gives the following information: \( I_{DSS} = 3 \, mA \), \( V_{GS\,(off)} = -6V \) and \( g_{m\,(max)} = 5000 \, \mu S \). Determine the transconductance for \( V_{GS} = -4V \) and find drain current \( I_D \) at this point.

**Solution.** At \( V_{GS} = 0 \), the value of \( g_m \) is maximum i.e. \( g_{mo} \).
\[ g_{mo} = 5000 \, \mu S \]

Now
\[ g_m = g_{mo} \left( 1 - \frac{V_{GS}}{V_{GS\,(off)}} \right) \]
\[ = 5000 \, \mu S \left( 1 - \frac{-4V}{-6V} \right) \]
\[ = 5000 \, \mu S \left( \frac{1}{3} \right) = 1667 \, \mu S \]

Also
\[ I_D = I_{DSS} \left( 1 - \frac{V_{GS}}{V_{GS\,(off)}} \right)^2 \]
\[ = 3 \, mA \left( 1 - \frac{-4}{-6} \right)^2 = 333 \, \mu A \]

### 19.16 JFET Biasing

For the proper operation of \( n \)-channel JFET, gate must be negative \( w.r.t. \) source. This can be achieved either by inserting a battery in the gate circuit or by a circuit known as biasing circuit. The latter method is preferred because batteries are costly and require frequent replacement.

1. **Bias battery.** In this method, JFET is biased by a bias battery \( V_{GG} \). This battery ensures that gate is always negative \( w.r.t. \) source during all parts of the signal.

2. **Biasing circuit.** The biasing circuit uses supply voltage \( V_{DD} \) to provide the necessary bias. Two most commonly used methods are (i) self-bias (ii) potential divider method. We shall discuss each method in turn.
Principles of Electronics

19.17 JFET Biasing by Bias Battery

Fig. 19.18 shows the biasing of a n-channel JFET by a bias battery \(-V_{GG}\). This method is also called gate bias. The battery voltage \(-V_{GG}\) ensures that gate – source junction remains reverse biased.

Since there is no gate current, there will be no voltage drop across \(R_G\).

\[ V_{GS} = V_{GG} \]

We can find the value of drain current \(I_D\) from the following relation:

\[ I_D = I_{DSS} \left(1 - \frac{V_{GS}}{V_{GS(\text{off})}}\right)^2 \]

The value of \(V_{DS}\) is given by:

\[ V_{DS} = V_{DD} - I_D R_D \]

Thus the d.c. values of \(I_D\) and \(V_{DS}\) stand determined. The operating point for the circuit is \(V_{DS}, I_D\).

Example 19.12. A JFET in Fig. 19.19 has values of \(V_{GS(\text{off})} = -8 \text{V}\) and \(I_{DSS} = 16 \text{mA}\). Determine the values of \(V_{GS}, I_D\) and \(V_{DS}\) for the circuit.

Solution. Since there is no gate current, there will be no voltage drop across \(R_G\).

\[ V_{GS} = V_{GG} = -5 \text{V} \]

Now

\[ I_D = I_{DSS} \left(1 - \frac{V_{GS}}{V_{GS(\text{off})}}\right)^2 \]

\[ = 16 \text{mA} \left(1 - \frac{-5}{-8}\right)^2 \]

\[ = 16 \text{mA} \times 0.1406 = 2.25 \text{mA} \]

Also

\[ V_{DS} = V_{DD} - I_D R_D \]

\[ = 10 \text{V} - 2.25 \text{mA} \times 2.2 \text{k}\Omega = 5.05 \text{V} \]

Note that operating point for the circuit is 5.05V, 2.25 mA.

19.18 Self-Bias for JFET

Fig. 19.20 shows the self-bias method for n-channel JFET. The resistor \(R_S\) is the bias resistor. The d.c. component of drain current flowing through \(R_S\) produces the desired bias voltage.

Voltage across \(R_S\), \(V_S = I_D R_S\)

Since gate current is negligibly small, the gate terminal is at d.c. ground i.e., \(V_G = 0\).

\[ V_{GS} = V_G - V_S = 0 - I_D R_S \]

or

\[ V_{GS} = -I_D R_S \]

Thus bias voltage \(V_{GS}\) keeps gate negative w.r.t. source.

\[ V_{GS} = V_G - V_S = \text{Negative. This means that } V_G \text{ is negative w.r.t. } V_S \]

Thus if \(V_G = 2\text{V}\) and \(V_S = 4\text{V}\), then \(V_{GS} = 2 - 4 = -2\text{V}\) i.e. gate is less positive than the source. Again if \(V_G = 0\text{V}\) and \(V_S = 2\text{V}\), then \(V_{GS} = 0 - 2 = -2\text{V}\). Note that \(V_G\) is less positive than \(V_S\).
Operating point. The operating point (i.e., zero signal \( I_D \) and \( V_{DS} \)) can be easily determined. Since the parameters of the JFET are usually known, zero signal \( I_D \) can be calculated from the following relation:

\[
I_D = I_{DSS} \left(1 - \frac{V_{GS}}{V_{GS(\text{off})}}\right)^2
\]

Also

\[
V_{DS} = V_{DD} - I_D (R_D + R_S)
\]

Thus d.c. conditions of JFET amplifier are fully specified i.e. operating point for the circuit is \( V_{DS}, I_D \).

Also,

\[
R_S = \left|\frac{V_{GS}}{I_D}\right|
\]

Note that gate resistor \( R_G \) does not affect bias because voltage across it is zero.

Midpoint Bias. It is often desirable to bias a JFET near the midpoint of its transfer characteristic curve where \( I_D = \frac{I_{DSS}}{2} \). When signal is applied, the midpoint bias allows a maximum amount of drain current swing between \( I_{DSS} \) and 0. It can be proved that when \( V_{GS} = V_{GS(\text{off})}/3.4 \), midpoint bias conditions are obtained for \( I_D \).

\[
I_D = I_{DSS} \left(1 - \frac{V_{GS}}{V_{GS(\text{off})}}\right)^2 = I_{DSS} \left(1 - \frac{V_{GS(\text{off})}}{V_{GS(\text{off})}}/3.4\right)^2 = 0.5 I_{DSS}
\]

To set the drain voltage at midpoint (\( V_D = V_{DD}/2 \)), select a value of \( R_D \) to produce the desired voltage drop.

Example 19.13. Find \( V_{DS} \) and \( V_{GS} \) in Fig. 19.21, given that \( I_D = 5 \text{ mA} \).

Solution.

\[
V_S = I_D R_S = (5 \text{ mA}) (470 \text{ Ω}) = 2.35 \text{ V}
\]

and

\[
V_D = V_{DD} - I_D R_D = 15 \text{ V} - (5 \text{ mA}) \times (1 \text{ kΩ}) = 10 \text{ V}
\]

\[
V_{DS} = V_D - V_S = 10 \text{ V} - 2.35 \text{ V} = 7.65 \text{ V}
\]

Since there is no gate current, there will be no voltage drop across \( R_G \) and \( V_G = 0 \).

Now

\[
V_{GS} = V_G - V_S = 0 - 2.35 \text{ V} = -2.35 \text{ V}
\]

Example 19.14. The transfer characteristic of a JFET reveals that when \( V_{GS} = -5 \text{ V} \), \( I_D = 6.25 \text{ mA} \). Determine the value of \( R_S \) required.

Solution.

\[
R_S = \left|\frac{V_{GS}}{I_D}\right| = \left|\frac{5 \text{ V}}{6.25 \text{ mA}}\right| = 800 \text{ Ω}
\]

Example 19.15. Determine the value of \( R_S \) required to self-bias a p-channel JFET with \( I_{DSS} = 25 \text{ mA}, V_{GS(\text{off})} = 15 \text{ V} \) and \( V_{GS} = 5 \text{ V} \).

Solution.

\[
I_D = I_{DSS} \left(1 - \frac{V_{GS}}{V_{GS(\text{off})}}\right)^2 = 25 \text{ mA} \left(1 - \frac{5 \text{ V}}{15 \text{ V}}\right)^2 = 25 \text{ mA} (1 - 0.333)^2 = 11.1 \text{ mA}
\]

\[
R_S = \left|\frac{V_{GS}}{I_D}\right| = \left|\frac{5 \text{ V}}{11.1 \text{ mA}}\right| = 450 \text{ Ω}
\]

\( R_G \) is necessary only to isolate an a.c. signal from ground in amplifier applications.
Example 19.16. Select resistor values in Fig. 19.22 to set up an approximate midpoint bias. The JFET parameters are: \( I_{\text{DSS}} = 15 \text{ mA} \) and \( V_{\text{GS (off)}} = -8 \text{ V} \). The voltage \( V_D \) should be 6V (one-half of \( V_{\text{DD}} \)).

Solution. For midpoint bias, we have,

\[
I_D = \frac{I_{\text{DSS}}}{2} = \frac{15 \text{ mA}}{2} = 7.5 \text{ mA}
\]

and

\[
V_{\text{GS}} = \frac{V_{\text{GS (off)}}}{3.4} = \frac{-8}{3.4} = -2.35 \text{ V}
\]

∴

\[
R_S = \frac{|V_{\text{DS}}|}{|I_D|} = \frac{2.35 \text{ V}}{7.5 \text{ mA}} = 313 \Omega
\]

Now

\[
V_D = V_{\text{DD}} - I_D R_D
\]

∴

\[
R_D = \frac{V_{\text{DD}} - V_D}{I_D} = \frac{12 \text{ V} - 6 \text{ V}}{7.5 \text{ mA}} = 800 \Omega
\]

Example 19.17. In a self-bias n-channel JFET, the operating point is to be set at \( I_D = 1.5 \text{ mA} \) and \( V_{\text{DS}} = 10 \text{ V} \). The JFET parameters are \( I_{\text{DSS}} = 5 \text{ mA} \) and \( V_{\text{GS (off)}} = -2 \text{ V} \). Find the values of \( R_S \) and \( R_D \) given that \( V_{\text{DD}} = 20 \text{ V} \).

Solution. Fig. 19.23 shows the circuit arrangement.

\[
I_D = I_{\text{DSS}} \left( 1 - \frac{V_{\text{GS}}}{V_{\text{GS (off)}}} \right)^2
\]

or

\[
1.5 = 5 \left( 1 - \frac{V_{\text{GS}}}{2} \right)^2
\]

or

\[
1 + \frac{V_{\text{GS}}}{2} = \sqrt{1.5/5} = 0.55
\]

or

\[
V_{\text{GS}} = -0.9 \text{ V}
\]

Now

\[
V_{\text{GS}} = V_G - V_S
\]

or

\[
V_S = V_G - V_{\text{GS}}
\]

\[
= 0 - (-0.9) = 0.9 \text{ V}
\]

∴

\[
R_S = \frac{V_S}{I_D} = \frac{0.9 \text{ V}}{1.5 \text{ mA}} = 0.6 \text{ k} \Omega
\]

Applying Kirchhoff’s voltage law to the drain circuit, we have,

\[
V_{\text{DD}} = I_D R_D + V_{\text{DS}} + I_D R_S
\]

or

\[
20 = 1.5 \text{ mA} \times R_D + 10 + 0.9
\]

∴

\[
R_D = \frac{(20 - 10 - 0.9) \text{ V}}{1.5 \text{ mA}} = 6 \text{ k} \Omega
\]

Example 19.18. In the JFET circuit shown in Fig. 19.24, find (i) \( V_{\text{DS}} \) and (ii) \( V_{\text{GS}} \).

Solution.

(i) \( V_{\text{DS}} = V_{\text{DD}} - I_D (R_D + R_S) = 30 - 2.5 \text{ mA} (5 + 0.2) = 30 - 13 = 17 \text{ V} \)

(ii) \( V_{\text{GS}} = -I_D R_S = -(2.5 \times 10^{-3}) \times 200 = -0.5 \text{ V} \)
Example 19.19. Figure 19.25 shows two stages of JFET amplifier. The first stage has $I_{D} = 2.15\text{mA}$ and the second stage has $I_{D} = 9.15\text{mA}$. Find the d.c. voltage of drain and source of each stage w.r.t. ground.

Solution. Voltage drop in $8.2\text{k}\Omega = 2.15\text{mA} \times 8.2\text{k}\Omega = 17.63\text{V}$

D.C. potential of drain of first stage w.r.t. ground is

$$V_{D} = V_{DD} - 17.63 = 30 - 17.63 = 12.37\text{V}$$

D.C. potential of source of first stage to ground is

$$V_{S} = I_{D}R_{S} = 2.15\text{mA} \times 0.68\text{k}\Omega = 1.46\text{V}$$

Voltage drop in $2\text{k}\Omega = 9.15\text{mA} \times 2\text{k}\Omega = 18.3\text{V}$

D.C. potential of drain of second stage to ground is

$$V_{D} = V_{DD} - 18.3 = 30 - 18.3 = 11.7\text{V}$$
Principles of Electronics

D.C. potential of source of second stage to ground is

\[ V_S = I_D R_S = 9.15 \text{ mA} \times 0.22 \text{ k}\Omega = 2.01 \text{ V} \]

19.19 JFET with Voltage-Divider Bias

Fig. 19.26 shows potential divider method of biasing a JFET. This circuit is identical to that used for a transistor. The resistors \( R_1 \) and \( R_2 \) form a voltage divider across \( V_{DD} \). The voltage \( V_2 \) (= \( V_G \)) across \( R_2 \) provides the necessary bias.

\[ V_2 = V_G = \frac{V_{DD}}{R_1 + R_2} \times R_2 \]

Now \[ V_2 = V_{GS} + I_D R_S \]

or \[ V_{GS} = V_2 - I_D R_S \]

The circuit is so designed that \( I_D R_S \) is larger than \( V_2 \) so that \( V_{GS} \) is negative. This provides correct bias voltage. We can find the operating point as under:

\[ I_D = \frac{V_2 - V_{GS}}{R_S} \]

and \[ V_{DS} = V_{DD} - I_D (R_D + R_S) \]

Although the circuit of voltage-divider bias is a bit complex, yet the advantage of this method of biasing is that it provides good stability of the operating point. The input impedance \( Z_i \) of this circuit is given by:

\[ Z_i = R_1 || R_2 \]

**Example 19.20.** Determine \( I_D \) and \( V_{GS} \) for the JFET with voltage-divider bias in Fig. 19.27, given that \( V_D = 7\text{ V} \).

**Solution.**

\[ I_D = \frac{V_{DD} - V_D}{R_D} = \frac{12\text{ V} - 7\text{ V}}{3.3 \text{ k}\Omega} = \frac{5\text{ V}}{3.3 \text{ k}\Omega} = 1.52 \text{ mA} \]

\[ V_S = I_D R_S = (1.52 \text{ mA}) (1.8 \text{ k}\Omega) = 2.74\text{ V} \]

\[ V_G = \frac{V_{DD}}{R_1 + R_2} \times R_2 = \frac{12\text{ V}}{7.8 \text{ M}\Omega} \times 1 \text{ M}\Omega = 1.54\text{ V} \]

\[ V_{GS} = V_G - V_S = 1.54\text{ V} - 2.74\text{ V} = -1.2\text{ V} \]

**Example 19.21.** In an n-channel JFET biased by potential divider method, it is desired to set the operating point at \( I_D = 2.5 \text{ mA} \) and \( V_{DS} = 8\text{ V} \). If \( V_{DD} = 30\text{ V} \), \( R_1 = 1 \text{ M}\Omega \) and \( R_2 = 500 \text{ k}\Omega \), find the value of \( R_S \). The parameters of JFET are \( I_{DSS} = 10 \text{ mA} \) and \( V_{GS(off)} = -5\text{ V} \).

**Solution.**

Fig. 19.28 shows the conditions of the problem.
\[ I_D = I_{DSS} \left(1 - \frac{V_{GS}}{V_{DSS \text{ (off)}}} \right)^2 \]

or \[ 2.5 = 10 \left(1 + \frac{V_{GS}}{5}\right)^2 \]

or \[ 1 + \frac{V_{GS}}{5} = \sqrt{2.5/10} = 0.5 \]

or \[ V_{GS} = -2.5 \text{ V} \]

Now, \[ V_2 = \frac{V_{DD}}{R_1 + R_2} \times R_2 \]

\[ = \frac{30}{1000 + 500} \times 500 \]

\[ = 10 \text{ V} \]

Now \[ V_2 = V_{GS} + I_D R_S \]

or \[ 10 \text{ V} = -2.5 \text{ V} + 2.5 \text{ mA} \times R_S \]

\[ \therefore R_S = \frac{10 \text{ V} + 2.5 \text{ V}}{2.5 \text{ mA}} = \frac{12.5 \text{ V}}{2.5 \text{ mA}} \]

\[ = 5 \text{ k}\Omega \]

**19.20 JFET Connections**

There are three leads in a JFET viz., source, gate and drain terminals. However, when JFET is to be connected in a circuit, we require four terminals; two for the input and two for the output. This difficulty is overcome by making one terminal of the JFET common to both input and output terminals. Accordingly, a JFET can be connected in a circuit in the following three ways:

(i) Common source connection

(ii) Common gate connection

(iii) Common drain connection

The common source connection is the most widely used arrangement. It is because this connection provides high input impedance, good voltage gain and a moderate output impedance. However, the circuit produces a phase reversal i.e., output signal is 180° out of phase with the input signal. Fig. 19.29 shows a common source n-channel JFET amplifier. Note that source terminal is common to both input and output.

**Note.** A common source JFET amplifier is the JFET equivalent of common emitter amplifier. Both amplifiers have a 180° phase shift from input to output. Although the two amplifiers serve the same basic purpose, the means by which they operate are quite different.

**19.21 Practical JFET Amplifier**

It is important to note that a JFET can accomplish faithful amplification only if proper associated circuitry is used. Fig. 19.29 shows the practical circuit of a JFET. The gate resistor \( R_G \) serves two purposes. It keeps the gate at approximately 0 V dc (Q gate current is nearly zero) and its large value (usually several megaohms) prevents loading of the a.c. signal source. The bias voltage is created by the drop across \( R_S \). The bypass capacitor \( C_S \) bypasses the a.c. signal and thus keeps the source of the JFET effectively at a.c. ground. The coupling capacitor \( C_{in} \) couples the signal to the input of JFET amplifier.
19.22 D.C. and A.C. Equivalent Circuits of JFET

Like in a transistor amplifier, both d.c. and a.c. conditions prevail in a JFET amplifier. The d.c. sources set up d.c. currents and voltages whereas the a.c. source (i.e. signal) produces fluctuations in the JFET currents and voltages. Therefore, a simple way to analyse the action of a JFET amplifier is to split the circuit into two parts viz. d.c. equivalent circuit and a.c. equivalent circuit. The d.c. equivalent circuit will determine the operating point (d.c. bias levels) for the circuit while a.c. equivalent circuit determines the output voltage and hence voltage gain of the circuit.

We shall split the JFET amplifier shown in Fig. 19.30 into d.c. and a.c. equivalent circuits. Note that biasing is provided by voltage-divider circuit.

**1. D.C. equivalent circuit.** In the d.c. equivalent circuit of a JFET amplifier, only d.c. conditions are considered i.e. it is presumed that no signal is applied. As direct current cannot
flow through a capacitor, all the capacitors look like open circuits in the d.c. equivalent circuit. It follows, therefore, that in order to draw the d.c. equivalent circuit, the following two steps are applied to the JFET amplifier circuit:

(i) Reduce all a.c. sources to zero.
(ii) Open all the capacitors.

Applying these two steps to the JFET amplifier circuit shown in Fig. 19.30, we get the d.c. equivalent circuit shown in Fig. 19.31. We can easily calculate the d.c. currents and voltages from this circuit.

2. A.C. equivalent circuit. In the a.c. equivalent circuit of a JFET amplifier, only a.c. conditions are to be considered. Obviously, the d.c. voltage is not important for such a circuit and may be considered zero. The capacitors are generally used to couple or bypass the a.c. signal. The designer intentionally selects capacitors that are large enough to appear as short circuits to the a.c. signal. It follows, therefore, that in order to draw the a.c. equivalent circuit, the following two steps are applied to the JFET amplifier circuit:

(i) Reduce all d.c. sources to zero (i.e. $V_{DD} = 0$).
(ii) Short all the capacitors.

Applying these two steps to the circuit shown in Fig. 19.30, we get the a.c. equivalent circuit shown in Fig. 19.32. We can easily calculate the a.c. currents and voltages from this circuit.

### 19.23 D.C. Load Line Analysis

The operating point of a JFET amplifier can be determined graphically by drawing d.c. load line on the drain characteristics ($V_{DS} - I_D$ curves). This method is identical to that used for transistors.

The d.c. equivalent circuit of a JFET amplifier using voltage-divider bias is shown in Fig. 19.33. It is clear that:

$$V_{DD} = V_{DS} + I_D(R_D + R_s)$$

or

$$V_{DS} = V_{DD} - I_D(R_D + R_s)$$

... (i)

---

* Note that one end of $R_1$ and $R_2$ is connected to one point (See Fig. 19.32) and the other end of $R_1$ and $R_2$ is connected to ground. Therefore, $R_1 \parallel R_2$. Similar is the case with $R_D$ and $R_L$ so that $R_D \parallel R_L$. 
Fig. 19.33

As for a given circuit, $V_{DD}$ and $(R_D + R_S)$ are constant, therefore, exp. (i) is a first degree equation and can be represented by a straight line on the drain characteristics. This is known as d.c. load line for JFET and determines the locus of $I_D$ and $V_{DS}$ (i.e. operating point) in the absence of the signal. The d.c. load line can be readily plotted by locating the two end points of the straight line.

(i) The value of $V_{DS}$ will be maximum when $I_D = 0$. Therefore, by putting $I_D = 0$ in exp. (i) above, we get,

$$\text{Max. } V_{DS} = V_{DD}$$

This locates the first point B ($OB = V_{DD}$) of the d.c. load line on drain-source voltage axis.

(ii) The value of $I_D$ will be maximum when $V_{DS} = 0$.

$$\therefore \text{Max. } I_D = \frac{V_{DD}}{R_D + R_S}$$

This locates the second point A ($OA = V_{DD}/(R_D + R_S)$) of the d.c. load line on drain current axis.

By joining points A and B, d.c. load line $AB$ is constructed [See Fig. 19.33 (ii)].

The operating point $Q$ is located at the intersection of the d.c. load line and the drain curve which corresponds to $V_{GS}$ provided by biasing. If we assume in Fig. 19.33 (i) that $V_{GS} = -2V$, then point $Q$ is located at the intersection of the d.c. load line and the $V_{GS} = -2V$ curve as shown in Fig. 19.33 (ii). The $I_D$ and $V_{DS}$ of $Q$ point are marked on the graph.

**Example 19.22.** Draw the d.c. load line for the JFET amplifier shown in Fig. 19.34 (i).

Fig. 19.34
Solution. To draw d.c. load line, we require two end points viz., max. $V_{DS}$ and max. $I_D$ points.

Max. $V_{DS} = V_{DD} = 20V$

This locates point $B$ ($OB = 20V$) of the d.c. load line.

Max. $I_D = \frac{V_{DD}}{R_D + R_S} = \frac{20V}{(150 + 50) \Omega}$

$= 20V = 100 mA$

This locates point $A$ ($OA = 100 mA$) of the d.c. load line. Joining $A$ and $B$, d.c. load line $AB$ is constructed as shown in Fig. 19.34 (ii).

Example 19.23. Draw the d.c. load line for the JFET amplifier shown in Fig. 19.35 (i).

Solution. Max. $V_{DS} = V_{DD} = 20V$

This locates the point $B$ ($OB = 20V$) of the d.c. load line.

Max. $I_D = \frac{V_{DD}}{R_D} = \frac{20V}{500 \Omega} = 40 mA$

This locates the point $A$ ($OA = 40 mA$) of the d.c. load line. Fig. 19.35 (ii) shows the d.c. load line $AB$.

19.24 Voltage Gain of JFET Amplifier

The a.c. equivalent circuit of JFET amplifier was developed in Art. 19.22 and is redrawn as Fig. 19.36 (i) for facility of reference. Note that $R_1 \parallel R_2$ and can be replaced by a single resistance $R_T$. Similarly, $R_D \parallel R_S$ and can be replaced by a single resistance $R_{AC}$ (= total a.c. drain resistance). The a.c. equivalent circuit shown in Fig. 19.36 (i) then reduces to the one shown in Fig. 19.36 (ii).

We now find the expression for voltage gain of this amplifier. Referring to Fig. 19.36 (ii), output voltage ($v_{out}$) is given by ;

$v_{out} = i_d R_{AC}$

... (i)

Remember that we define $g_m$ as :
Putting the value of $i_d = \frac{g_m V_{gs}}{v_{gs}}$ in eq. (i), we have,

$$V_{out} = g_m V_{in} R_{AC}$$

Now $v_{in} = V_{gs}$ so that a.c. output voltage is

$$V_{out} = g_m V_{in} R_{AC}$$

or

$$\frac{V_{out}}{V_{in}} = g_m R_{AC}$$

But $\frac{V_{out}}{V_{in}}$ is the voltage gain ($A_v$) of the amplifier.

∴ Voltage gain, $A_v = g_m R_{AC}$ ... for loaded amplifier

$= g_m R_D$ ... for unloaded amplifier

Example 19.24. The JFET in the amplifier of Fig. 19.37 has a transconductance $g_m = 1 \text{ mA/V}$. If the source resistance $R_S$ is very small as compared to $R_G$, find the voltage gain of the amplifier.

Solution.

Transconductance of JFET, $g_m = 1 \text{ mA/V}$
Field Effect Transistors

\[531\]

The total ac load (i.e. \(R_{AC}\)) in the drain circuit consists of the parallel combination of \(R_D\) and \(R_L\), i.e.

\[
R_{AC} = R_D \parallel R_L
\]

\[
= 12 \, \text{k}\Omega \parallel 8 \, \text{k}\Omega = \frac{12 \times 8}{12 + 8} = 4.8 \, \text{k}\Omega
\]

\[\therefore \text{Voltage gain, } A_v = g_m \times R_{AC}\]

\[
= (1000 \times 10^{-6}) \times (4.8 \times 10^3) = 4.8
\]

**Example 19.25.** The transconductance of a JFET used as a voltage amplifier is 3000 \(\mu\text{mho}\) and drain resistance is 10 \(\text{k}\Omega\). Calculate the voltage gain of the amplifier.

**Solution.**

Transconductance of JFET, \(g_m = 3000 \, \mu\text{mho} = 3000 \times 10^{-6} \, \text{mho}\)

Drain resistance, \(R_D = 10 \, \text{k}\Omega = 10 \times 10^3 \, \Omega\)

\[\therefore \text{Voltage gain, } A_v = g_m R_D = (3000 \times 10^{-6}) (10 \times 10^3) = 30\]

**Example 19.26.** What is the r.m.s. output voltage of the unloaded amplifier in Fig. 19.38? The \(I_{DSS} = 8 \, \text{mA}, V_{GS\text{ (off)}} = -10 \text{V}\) and \(I_D = 1.9 \, \text{mA}\).

**Solution.**

\[V_{GS} = -I_D R_S = -1.9 \, \text{mA} \times 2.7 \times 10^3 \, \Omega = -5.13 \text{V}\]

\[g_{mo} = \frac{2 I_{DSS}}{|V_{GS\text{ (off)}}|} = \frac{2 \times 8 \, \text{mA}}{10 \, \text{V}} = 1.6 \times 10^{-3} \, \text{S}\]

\[\therefore g_m = g_{mo} \left(1 - \frac{V_{GS}}{V_{GS\text{ (off)}}}\right) = 1.6 \times 10^{-3} \left(1 - \frac{5.13 \, \text{V}}{-10 \, \text{V}}\right) = 779 \times 10^{-6} \, \text{S}\]

Voltage gain, \(A_v = g_m R_D = (779 \times 10^{-6}) (3.3 \times 10^3) = 2.57\)

\[\therefore \text{Output voltage, } v_{out} = A_v v_{in} = 2.57 \times 100 \, \text{mV} = 257 \, \text{mV (r.m.s.)}\]

**Example 19.27.** If a 4.7 \(\text{k}\Omega\) load resistor is a.c. coupled to the output of the amplifier in Fig. 19.38 above, what is the resulting r.m.s. output voltage?

**Solution.** The value of \(g_m\) remains the same. However, the value of total a.c. drain resistance \(R_{AC}\) changes due to the connection of load \(R_L = (4.7 \, \text{k}\Omega)\).

Total a.c. drain resistance, \(R_{AC} = R_D \parallel R_L\)
Principles of Electronics

\[
\frac{R_D R_L}{R_D + R_L} = \frac{(3.3 \, \text{k} \Omega) (4.7 \, \text{k} \Omega)}{3.3 \, \text{k} \Omega + 4.7 \, \text{k} \Omega} = 1.94 \, \text{k} \Omega
\]

\[\therefore \text{Voltage gain, } A_v = g_m R_{AC} = (779 \times 10^{-6}) (1.94 \times 10^3) = 1.51\]

Output voltage, \(v_{out} = A_v v_m = 1.51 \times 100 \, \text{mV} = 151 \, \text{mV (r.m.s.)}\)

19.25 Voltage Gain of JFET Amplifier (With Source Resistance \(R_S\))

Fig. 19.39 (i) shows the JFET amplifier with source resistor \(R_S\) unbypassed. This means that a.c. signal will not be bypassed by the capacitor \(C_S\).

Fig. 19.39 (ii) shows the simplified a.c. equivalent circuit of the JFET amplifier. Since \(g_m = |d|/v_{gs}\), a current source \(i_d = g_m v_{gs}\) appears between drain and source. Referring to Fig. 19.39 (ii),

\[
v_{in} = v_{gs} + i_d R_S
\]

\[
v_{out} = \frac{v_{out}}{v_{in}} = \frac{i_d R_D}{v_{gs} + i_d R_S}
\]

\[\therefore \text{Voltage gain, } A_v = \frac{g_m v_{gs} R_D}{v_{gs} (1 + g_m R_S)} = \frac{g_m v_{gs} R_D}{v_{gs} (1 + g_m R_S)} \quad \text{(Q } i_d = g_m v_{gs})\]

\[\therefore A_v = \frac{g_m R_D}{1 + g_m R_S} \quad \text{... for unloaded amplifier}
\]

\[= \frac{g_m R_{AC}}{1 + g_m R_S} \quad \text{... for loaded amplifier}
\]

Note that \(R_{AC} (= R_D \parallel R_L)\) is the total a.c. drain resistance.

**Example 19.28.** In a JFET amplifier, the source resistance \(R_S\) is unbypassed. Find the voltage gain of the amplifier. Given \(g_m = 4 \, \text{mS} \); \(R_D = 1.5 \, \text{k} \Omega\) and \(R_S = 560 \, \Omega\).

**Solution.**

Voltage gain, \(A_v = \frac{g_m R_D}{1 + g_m R_S}\)

Here \(g_m = 4 \, \text{mS} = 4 \times 10^{-3} \, \text{S} \); \(R_D = 1.5 \, \text{k} \Omega = 1.5 \times 10^3 \, \Omega \); \(R_S = 560 \, \Omega\)
Field Effect Transistors

\[ A_v = \frac{(4 \times 10^{-3})(1.5 \times 10^3)}{1 + (4 \times 10^{-3})(560)} = \frac{6}{1 + 2.24} = 1.85 \]

If \( R_S \) is bypassed by a capacitor, then,

\[ A_v = g_m R_D = (4 \times 10^{-3})(1.5 \times 10^3) = 6 \]

Thus with unbypassed \( R_S \), the gain is 1.85 whereas with \( R_S \) bypassed by a capacitor, the gain is 6. Therefore, voltage gain is reduced when \( R_S \) is unbypassed.

**Example 19.29.** For the JFET amplifier circuit shown in Fig. 19.40, calculate the voltage gain with (i) \( R_S \) bypassed by a capacitor (ii) \( R_S \) unbypassed.

![Fig. 19.40](image)

**Solution.** From the d.c. bias analysis, we get, \( I_D = 2.3 \) mA and \( V_{GS} = -1.8 \) V.

The value of \( g_m \) is given by;

\[ g_m = \frac{2 I_{DSS}}{|V_{GS\ (off)}|} \left[ 1 - \frac{V_{GS}}{V_{GS\ (off)}} \right] \]

\[ = \frac{2 \times 10^{-3}}{3.5} \left[ 1 - \frac{-1.8}{-3.5} \right] = (5.7 \text{ mS}) (0.486) = 2.77 \text{ mS} \]

(i) The voltage gain with \( R_S \) bypassed is

\[ A_v = g_m R_D = (2.77 \text{ mS})(1.5 \text{ k\Omega}) = 4.155 \]

(ii) The voltage gain with \( R_S \) unbypassed is

\[ A_v = \frac{g_m R_D}{1 + g_m R_S} = \frac{4.155}{1 + (2.77 \text{ mS})(0.75 \text{ k\Omega})} = 1.35 \]

**19.26 JFET Applications**

The high input impedance and low output impedance and low noise level make JFET far superior to the bipolar transistor. Some of the circuit applications of JFET are:

- \( I_D = I_{DSS} \left[ 1 - \frac{V_{GS}}{V_{GS\ (off)}} \right]^2 \) and \( V_{GS} = -I_D R_S \)

The unknown quantities \( V_{GS} \) and \( I_D \) can be found from these two equations.
(i) **As a buffer amplifier.** A buffer amplifier is a stage of amplification that isolates the preceding stage from the following stage. Because of the high input impedance and low output impedance, a JFET can act as an excellent buffer amplifier (See Fig. 19.41). The high input impedance of JFET means light loading of the preceding stage. This permits almost the entire output from first stage to appear at the buffer input. The low output impedance of JFET can drive heavy loads (or small load resistances). This ensures that all the output from the buffer reaches the input of the second stage.

![Fig. 19.41](image)

(ii) **Phase-shift oscillators.** The oscillators discussed in chapter 14 will also work with JFETs. However, the high input impedance of JFET is especially valuable in phase-shift oscillators to minimise the loading effect. Fig. 19.42 shows the phase-shift oscillator using n-channel JFET.

![Fig. 19.42](image)

(iii) **As RF amplifier.** In communication electronics, we have to use JFET RF amplifier in a receiver instead of BJT amplifier for the following reasons:

(a) The noise level of JFET is very low. The JFET will not generate significant amount of noise and is thus useful as an RF amplifier.

(b) The antenna of the receiver receives a very weak signal that has an extremely low amount of current. Since JFET is a voltage controlled device, it will well respond to low current signal provided by the antenna.
19.27 Metal Oxide Semiconductor FET (MOSFET)

The main drawback of JFET is that its gate must be reverse biased for proper operation of the device i.e. it can only have negative gate operation for n-channel and positive gate operation for p-channel. This means that we can only decrease the width of the channel (i.e. decrease the conductivity of the channel) from its zero-bias size. This type of operation is referred to as depletion-mode operation. Therefore, a JFET can only be operated in the depletion-mode. However, there is a field effect transistor (FET) that can be operated to enhance (or increase) the width of the channel (with consequent increase in conductivity of the channel) i.e. it can have enhancement-mode operation. Such a FET is called MOSFET.

A field effect transistor (FET) that can be operated in the enhancement-mode is called a MOSFET.

A MOSFET is an important semiconductor device and can be used in any of the circuits covered for JFET. However, a MOSFET has several advantages over JFET including high input impedance and low cost of production.

19.28 Types of MOSFETs

There are two basic types of MOSFETs viz.

1. Depletion-type MOSFET or D-MOSFET. The D-MOSFET can be operated in both the depletion-mode and the enhancement-mode. For this reason, a D-MOSFET is sometimes called depletion/enhancement MOSFET.

2. Enhancement-type MOSFET or E-MOSFET. The E-MOSFET can be operated only in enhancement-mode.

The manner in which a MOSFET is constructed determines whether it is D-MOSFET or E-MOSFET.

1. D-MOSFET. Fig. 19.43 shows the constructional details of n-channel D-MOSFET. It is similar to n-channel JFET except with the following modifications/remarks:

(i) The n-channel D-MOSFET is a piece of n-type material with a p-type region (called substrate) on the right and an insulated gate on the left as shown in Fig. 19.43. The free electrons (Q) it is n-channel) flowing from source to drain must pass through the narrow channel between the gate and the p-type region (i.e. substrate).

(ii) Note carefully the gate construction of D-MOSFET. A thin layer of metal oxide (usually silicon dioxide, SiO₂) is deposited over a small portion of the channel. A metallic gate is deposited over the oxide layer. As SiO₂ is an insulator, therefore, gate is insulated from the channel. Note that the arrangement forms a capacitor. One plate of this capacitor is the gate and the other plate is the channel with SiO₂ as the dielectric. Recall that we have a gate diode in a JFET.

(iii) It is a usual practice to connect the substrate to the source (S) internally so that a MOSFET has three terminals viz. source (S), gate (G) and drain (D).

(iv) Since the gate is insulated from the channel, we can apply either negative or positive voltage to the gate. Therefore, D-MOSFET can be operated in both depletion-mode and enhancement-mode. However, JFET can be operated only in depletion-mode.

* With the decrease in channel width, the X-sectional area of the channel decreases and hence its resistance increases. This means that conductivity of the channel will decrease. Reverse happens if channel width increases.

** With gate reverse biased, the channel is depleted (i.e. emptied) of charge carriers (free electrons for n-channel and holes for p-channel) and hence the name depletion-mode. Note that depletion means decrease. In this mode of operation, conductivity decreases from the zero-bias level.
2. **E-MOSFET.** Fig. 19.44 shows the constructional details of n-channel E-MOSFET. Its gate construction is similar to that of D-MOSFET. The E-MOSFET has no channel between source and drain unlike the D-MOSFET. Note that the substrate extends completely to the SiO₂ layer so that no channel exists. The E-MOSFET requires a proper gate voltage to form a channel (called induced channel). It is reminded that E-MOSFET can be operated only in enhancement mode. In short, the construction of E-MOSFET is quite similar to that of the D-MOSFET except for the absence of a channel between the drain and source terminals.

**Why the name MOSFET?** The reader may wonder why is the device called MOSFET? The answer is simple. The SiO₂ layer is an insulator. The gate terminal is made of a metal conductor. Thus, going from gate to substrate, you have a metal oxide semiconductor and hence the name MOSFET. Since the gate is insulated from the channel, the MOSFET is sometimes called insulated-gate FET (IGFET). However, this term is rarely used in place of the term MOSFET.

### 19.29 Symbols for D-MOSFET

There are two types of D-MOSFETs viz (i) n-channel D-MOSFET and (ii) p-channel D-MOSFET.

**i) n-channel D-MOSFET.** Fig. 19.45 (i) shows the various parts of n-channel D-MOSFET. The p-type substrate constrains the channel between the source and drain so that only a small passage...
remains at the left side. Electrons flowing from source (when drain is positive w.r.t. source) must pass through this narrow channel. The symbol for \textit{n-channel D-MOSFET} is shown in Fig. 19.45 (ii). The gate appears like a capacitor plate. Just to the right of the gate is a thick vertical line representing the channel. The drain lead comes out of the top of the channel and the source lead connects to the bottom. The arrow is on the substrate and points to the \textit{n}-material, therefore we have \textit{n-channel D-MOSFET}. It is a usual practice to connect the substrate to source internally as shown in Fig. 19.45 (iii). This gives rise to a three-terminal device.

\textbf{(ii) \textit{p-channel D-MOSFET}.} Fig. 19.46 (i) shows the various parts of \textit{p-channel D-MOSFET}. The \textit{n}-type substrate constricts the channel between the source and drain so that only a small passage remains at the left side. The conduction takes place by the flow of holes from source to drain through this narrow channel. The symbol for \textit{p-channel D-MOSFET} is shown in Fig. 19.46 (ii). It is a usual practice to connect the substrate to source internally. This results in a three-terminal device whose schematic symbol is shown in Fig. 19.46 (iii).

\begin{figure}[h]

  \includegraphics[width=\textwidth]{diagram.png}
  \caption{Fig. 19.46}
\end{figure}

\section*{19.30 Circuit Operation of D-MOSFET}

Fig. 19.47 (i) shows the circuit of \textit{n-channel D-MOSFET}. The gate forms a small capacitor. One plate of this capacitor is the gate and the other plate is the channel with metal oxide layer as the dielectric. When gate voltage is changed, the electric field of the capacitor changes which in turn changes the resistance of the \textit{n}-channel. Since the gate is insulated from the channel, we can apply either negative or positive voltage to the gate. The negative-gate operation is called \textit{depletion mode} whereas positive-gate operation is known as \textit{enhancement mode}.

\textbf{(i) \textit{Depletion mode}.} Fig. 19.47 (i) shows depletion-mode operation of \textit{n-channel D-MOSFET}. Since gate is negative, it means electrons are on the gate as shown is Fig. 19.47 (ii). These electrons repel the free electrons in the \textit{n}-channel, leaving a layer of positive ions in a part of the channel as shown in Fig. 19.47 (ii). In other words, we have depleted (i.e. emptied) the \textit{n}-channel of some of its free electrons. Therefore, lesser number of free electrons are made available for current conduction through the \textit{n}-channel. This is the same thing as if the resistance of the channel is increased. The greater the negative voltage on the gate, the lesser is the current from source to drain.

Thus by changing the negative voltage on the gate, we can vary the resistance of the \textit{n}-channel and hence the current from source to drain. Note that with negative voltage to the gate, the action of \textit{D-MOSFET} is similar to \textit{JFET}. Because the action with negative gate depends upon depleting (i.e. emptying) the channel of free electrons, the negative-gate operation is called \textit{depletion mode}.

\begin{itemize}
  \item \textbf{If one plate of the capacitor is negatively charged, it induces positive charge on the other plate.}
\end{itemize}
Note that gate of JFET is always reverse biased for proper operation. However, in a MOSFET, because of the insulating layer, a negligible gate current flows whether we apply negative or positive voltage to gate.

(ii) Enhancement mode. Fig. 19.48 (i) shows enhancement-mode operation of n-channel D-MOSFET. Again, the gate acts like a capacitor. Since the gate is positive, it induces negative charges in the n-channel as shown in Fig. 19.48 (ii). These negative charges are the free electrons drawn into the channel. Because these free electrons are added to those already in the channel, the total number of free electrons in the channel is increased. Thus a positive gate voltage enhances or increases the conductivity of the channel. The greater the positive voltage on the gate, greater the conduction from source to drain.

Thus by changing the positive voltage on the gate, we can change the conductivity of the channel. The main difference between D-MOSFET and JFET is that we can apply positive gate voltage to D-MOSFET and still have essentially *zero current. Because the action with a positive gate depends upon enhancing the conductivity of the channel, the positive gate operation is called enhancement mode.

The following points may be noted about D-MOSFET operation:

(i) In a D-MOSFET, the source to drain current is controlled by the electric field of capacitor formed at the gate.

(ii) The gate of JFET behaves as a reverse-biased diode whereas the gate of a D-MOSFET acts like a capacitor. For this reason, it is possible to operate D-MOSFET with positive or negative gate voltage.

(iii) As the gate of D-MOSFET forms a capacitor, therefore, negligible gate current flows whether...
positive or negative voltage is applied to the gate. For this reason, the input impedance of D-MOSFET is very high, ranging from 10,000 MΩ to 10,000,00 MΩ.

(iv) The extremely small dimensions of the oxide layer under the gate terminal result in a very low capacitance and the D-MOSFET has, therefore, a very low input capacitance. This characteristic makes the D-MOSFET useful in high-frequency applications.

19.31 D-MOSFET Transfer Characteristic

Fig. 19.49 shows the transfer characteristic curve (or transconductance curve) for n-channel D-MOSFET. The behaviour of this device can be beautifully explained with the help of this curve as under:

(i) The point on the curve where $V_{GS} = 0$, $I_D = I_{DSS}$. It is expected because $I_{DSS}$ is the value of $I_D$ when gate and source terminals are shorted i.e. $V_{GS} = 0$.

(ii) As $V_{GS}$ goes negative, $I_D$ decreases below the value of $I_{DSS}$ till $I_D$ reaches zero when $V_{GS} = V_{GS}^{\text{off}}$, just as with JFET.

(iii) When $V_{GS}$ is positive, $I_D$ increases above the value of $I_{DSS}$. The maximum allowable value of $I_D$ is given on the data sheet of D-MOSFET.

![Fig. 19.49](image)

Note that the transconductance curve for the D-MOSFET is very similar to the curve for a JFET. Because of this similarity, the JFET and the D-MOSFET have the same transconductance equation viz.

\[ I_D = I_{DSS} \left( 1 - \frac{V_{GS}}{V_{GS}^{\text{off}}} \right)^2 \]

**Example 19.30.** For a certain D-MOSFET, $I_{DSS} = 10$ mA and $V_{GS}^{\text{off}} = -8$ V.

(i) Is this an n-channel or a p-channel?

(ii) Calculate $I_D$ at $V_{GS} = -3$ V.

(iii) Calculate $I_D$ at $V_{GS} = +3$ V.

**Solution.**

(i) The device has a negative $V_{GS}^{\text{off}}$. Therefore, it is **n-channel D-MOSFET**.

(ii) $I_D = I_{DSS} \left( 1 - \frac{V_{GS}}{V_{GS}^{\text{off}}} \right)^2$

\[ = 10 \text{ mA} \left( 1 - \frac{-3}{-8} \right)^2 = 3.91 \text{ mA} \]
Example 19.31. A D-MOSFET has parameters of \( V_{GS\ (off)} = -6V \) and \( I_{DSS} = 1 mA \). How will you plot the transconductance curve for the device?

**Solution.** When \( V_{GS} = 0 V \), \( I_D = I_{DSS} = 1 mA \) and when \( V_{GS} = V_{GS\ (off)} \), \( I_D = 0 A \). This locates two points \( V_{GS\ (off)} \) and \( I_{DSS} \) on the transconductance curve. We can locate more points of the curve by changing \( V_{GS} \) values.

- When \( V_{GS} = -3V \); \( I_D = 1 mA \)
  \[
  \left(1 - \frac{-3V}{-6V}\right)^2 = 0.25 mA
  \]
- When \( V_{GS} = -1V \); \( I_D = 1 mA \)
  \[
  \left(1 - \frac{-1V}{-6V}\right)^2 = 0.694 mA
  \]
- When \( V_{GS} = +1V \); \( I_D = 1 mA \)
  \[
  \left(1 - \frac{+1V}{-6V}\right)^2 = 1.36 mA
  \]
- When \( V_{GS} = +3V \); \( I_D = 1 mA \)
  \[
  \left(1 - \frac{+3V}{-6V}\right)^2 = 2.25 mA
  \]

Thus we have a number of \( V_{GS} - I_D \) readings so that transconductance curve for the device can be readily plotted.

### 19.32 Transconductance and Input Impedance of D-MOSFET

These are important parameters of a D-MOSFET and a brief discussion on them is desirable.

(i) **D-MOSFET Transconductance \( g_m \).** The value of \( g_m \) is found for a D-MOSFET in the same way that it is for the JFET i.e.

\[
g_m = g_{mo} \left(1 - \frac{V_{GS}}{V_{GS\ (off)}}\right)
\]

(ii) **D-MOSFET Input Impedance.** The gate impedance of a D-MOSFET is extremely high. For example, a typical D-MOSFET may have a maximum gate current of 10 pA when \( V_{GS} = 35V \). Thus

\[
\text{Input impedance} = \frac{35V}{10 \text{ pA}} = \frac{35V}{10 \times 10^{-12} \text{ A}} = 3.5 \times 10^{12} \Omega
\]

With an input impedance in this range, D-MOSFET would present virtually no load to a source circuit.

### 19.33 D-MOSFET Biasing

The following methods may be used for D-MOSFET biasing:

(i) Gate bias
(ii) Self-bias
(iii) Voltage-divider bias
(iv) Zero bias

The first three methods are exactly the same as those used for JFETs and are not discussed here. However, the last method of zero-bias is widely used in D-MOSFET circuits.

**Zero bias.** Since a D-MOSFET can be operated with either positive or negative values of \( V_{GS} \), we can set its Q-point at \( V_{GS} = 0V \) as shown in Fig. 19.50. Then an input a.c. signal to the gate can produce variations above and below the Q-point.

* We can only change \( V_{GS} \) because the values of \( I_{DSS} \) and \( V_{GS\ (off)} \) are constant for a given D-MOSFET.
We can use the simple circuit of Fig. 19.51 to provide zero bias. This circuit has \( V_{GS} = 0 \) V and \( I_D = I_{DSS} \). We can find \( V_{DS} \) as under:

\[
V_{DS} = V_{DD} - I_{DSS} R_D
\]

Note that for the D-MOSFET zero bias circuit, the source resistor \( (R_S) \) is not necessary. With no source resistor, the value of \( V_S \) is 0V. This gives us a value of \( V_{GS} = 0 \) V. This biases the circuit at \( I_D = I_{DSS} \) and \( V_{GS} = 0 \) V. For mid-point biasing, the value of \( R_D \) is so selected that \( V_{DS} = V_{DD}/2 \).

**Example 19.32.** Determine the drain-to-source voltage \( (V_{DS}) \) in the circuit shown in Fig. 19.51 above if \( V_{DD} = +18 \) V and \( R_D = 620 \) \( \Omega \). The MOSFET data sheet gives \( V_{GS(\text{off})} = -8 \) V and \( I_{DSS} = 12 \) mA.

**Solution.** Since \( I_D = I_{DSS} = 12 \) mA, the \( V_{DS} \) is given by:

\[
V_{DS} = V_{DD} - I_{DSS} R_D = 18 \text{ V} - (12 \text{ mA})(0.62 \text{ k}\Omega) = 10.6 \text{ V}
\]

**19.34 Common-Source D-MOSFET Amplifier**

Fig. 19.52 shows a common-source amplifier using \( n \)-channel D-MOSFET. Since the source terminal is common to the input and output terminals, the circuit is called *common-source amplifier*. The circuit is zero biased with an a.c. source coupled to the gate through the coupling capacitor \( C_1 \). The gate is at approximately 0V d.c. and the source terminal is grounded, thus making \( V_{GS} = 0 \) V.
Principles of Electronics

Operation. The input signal \( V_{in} \) is capacitively coupled to the gate terminal. In the absence of the signal, d.c. value of \( V_{GS} = 0 \) V. When signal \( V_{in} \) is applied, \( V_{gs} \) swings above and below its zero value (Q d.c. value of \( V_{GS} = 0 \) V), producing a swing in drain current \( I_D \).

(i) A small change in gate voltage produces a large change in drain current as in a JFET. This fact makes MOSFET capable of raising the strength of a weak signal; thus acting as an amplifier.

(ii) During the positive half-cycle of the signal, the positive voltage on the gate increases and produces the enhancement-mode. This increases the channel conductivity and hence the drain current.

(iii) During the negative half-cycle of the signal, the positive voltage on the gate decreases and produces depletion-mode. This decreases the conductivity and hence the drain current.

The result of above action is that a small change in gate voltage produces a large change in the drain current. This large variation in drain current produces a large a.c. output voltage across drain resistance \( R_D \). In this way, D-MOSFET acts as an amplifier. Fig. 19.53 shows the amplifying action of D-MOSFET on transconductance curve.

Voltage gain. The a.c. analysis of D-MOSFET is similar to that of the JFET. Therefore, voltage gain expressions derived for JFET are also applicable to D-MOSFET.

\[
\text{Voltage gain, } A_v = g_m R_D \quad \text{... for unloaded D-MOSFET amplifier}
\]

\[
A_v = g_m R_{AC} \quad \text{... for loaded D-MOSFET amplifier}
\]

Note the total a.c. drain resistance \( R_{AC} = R_D \parallel R_L \).

Example 19.33. The D-MOSFET used in the amplifier of Fig. 19.54 has an \( I_{DSS} = 12 \) mA and \( g_m = 3.2 \) mS. Determine (i) d.c. drain-to-source voltage \( V_{DS} \) and (ii) a.c. output voltage. Given \( V_{in} = 500 \) mV.

Solution.

(i) Since the amplifier is zero biased, \( I_D = I_{DSS} = 12 \) mA.

\[
V_{DS} = V_{DD} - I_{DSS} R_D
\]

\[
= 15 \text{ V} - (12 \text{ mA}) (0.62 \text{ k}\Omega) = 7.56 \text{ V}
\]

(ii) Total a.c. drain resistance \( R_{AC} \) of the circuit is

\[
R_{AC} = R_D \parallel R_L = 620 \text{ \Omega} \parallel 8.2 \text{ k}\Omega = 576 \text{ \Omega}
\]

\[
V_{out} = A_v \times V_{in} = (g_m R_{AC}) (V_{in})
\]

\[
= (3.2 \times 10^{-3} \text{ S} \times 576 \text{ \Omega} \times 500 \text{ mV}) = 922 \text{ mV}
\]
19.35 D-MOSFETs Versus JFETs

Table below summarises many of the characteristics of JFETs and D-MOSFETs.

19.36 E-MOSFET

Two things are worth noting about E-MOSFET. First, E-MOSFET operates only in the enhancement mode and has no depletion mode. Secondly, the E-MOSFET has no physical channel from source to drain because the substrate extends completely to the SiO₂ layer [See Fig. 19.55 (i)]. It is only by the application of $V_{GS}$ (gate-to-source voltage) of proper magnitude and polarity that the device starts conducting. The minimum value of $V_{GS}$ of proper polarity that turns on the E-MOSFET is called Threshold voltage [$V_{GS(\text{th})}$]. The n-channel device requires positive $V_{GS}$ ($\geq V_{GS(\text{th})}$) and the p-channel device requires negative $V_{GS}$ ($\leq V_{GS(\text{th})}$).

**Operation.** Fig. 19.55 (i) shows the circuit of n-channel E-MOSFET. The circuit action is as under:

(i) When $V_{GS} = 0V$ [See Fig. 19.55(i)], there is no channel connecting the source and drain. The $p$ substrate has only a few thermally produced free electrons (minority carriers) so that drain current is essentially zero. For this reason, E-MOSFET is normally OFF when $V_{GS} = 0$ V. Note that this behaviour of E-MOSFET is quite different from JFET or D-MOSFET.
When gate is made positive (i.e. $V_{GS}$ is positive) as shown in Fig. 19.55 (ii), it attracts free electrons into the $p$ region. The free electrons combine with the holes next to the SiO$_2$ layer. If $V_{GS}$ is positive enough, all the holes touching the SiO$_2$ layer are filled and free electrons begin to flow from the source to drain. The effect is the same as creating a thin layer of $n$-type material (i.e. inducing a thin $n$-channel) adjacent to the SiO$_2$ layer. Thus the E-MOSFET is turned ON and drain current $I_D$ starts flowing from the source to the drain.

The minimum value of $V_{GS}$ that turns the E-MOSFET ON is called threshold voltage [$V_{GS\ (th)}$].

When $V_{GS}$ is less than $V_{GS\ (th)}$, there is no induced channel and the drain current $I_D$ is zero. When $V_{GS}$ is equal to $V_{GS\ (th)}$, the E-MOSFET is turned ON and the induced channel conducts drain current from the source to the drain. Beyond $V_{GS\ (th)}$, if the value of $V_{GS}$ is increased, the newly formed channel becomes wider, causing $I_D$ to increase. If the value of $V_{GS}$ decreases [not less than $V_{GS\ (th)}$], the channel becomes narrower and $I_D$ will decrease. This fact is revealed by the transconductance curve of $n$-channel E-MOSFET shown in Fig. 19.56. As you can see, $I_D = 0$ when $V_{GS} = 0$. Therefore, the value of $I_{DS\ SS}$ for the E-MOSFET is zero. Note also that there is no drain current until $V_{GS}$ reaches $V_{GS\ (th)}$.

**Equation for Transconductance Curve.** Fig. 19.58 shows the transconductance curve for $n$-channel E-MOSFET. Note that this curve is different from the transconductance curve for $n$-channel JFET or $n$-channel D-MOSFET. It is because it starts at $V_{GS\ (th)}$ rather than $V_{GS\ (off)}$ on the horizontal axis and never intersects the vertical axis. The equation for the E-MOSFET transconductance curve (for $V_{GS} > V_{GS\ (th)}$) is
The constant $K$ depends on the particular E-MOSFET and its value is determined from the following equation:

$$K = \frac{I_{D(on)}}{(V_{GS(on)} - V_{GS(th)})^2}$$

Any data sheet for an E-MOSFET will include the current $I_{D(on)}$ and the voltage $V_{GS(on)}$ for one point well above the threshold voltage as shown in Fig. 19.58.

**Example 19.34.** The data sheet for an E-MOSFET gives $I_{D(on)} = 500 \text{ mA}$ at $V_{GS} = 10 \text{ V}$ and $V_{GS(th)} = 1 \text{ V}$. Determine the drain current for $V_{GS} = 5 \text{ V}$.

**Solution.** Here $V_{GS(on)} = 10 \text{ V}$.

$$I_D = K (V_{GS} - V_{GS(th)})^2$$

Here

$$K = \frac{500 \text{ mA}}{(10 \text{ V} - 1 \text{ V})^2} = 6.17 \text{ mA/V}^2$$

Putting the various values in eq. (i), we have,

$$I_D = 6.17 (5 \text{ V} - 1 \text{ V})^2 = 98.7 \text{ mA}$$

**Example 19.35.** The data sheet for an E-MOSFET gives $I_{D(on)} = 3 \text{ mA}$ at $V_{GS} = 10 \text{ V}$ and $V_{GS(th)} = 3 \text{ V}$. Determine the resulting value of $K$ for the device. How will you plot the transconductance curve for this MOSFET?

**Solution.** The value of $K$ can be determined from the following equation:

$$K = \frac{I_{D(on)}}{(V_{GS(on)} - V_{GS(th)})^2}$$

Here

$$I_{D(on)} = 3 \text{ mA} ; V_{GS(on)} = 10 \text{ V} ; V_{GS(th)} = 3 \text{ V}$$

$$\therefore \quad K = \frac{3 \text{ mA}}{(10 \text{ V} - 3 \text{ V})^2} = \frac{3 \text{ mA}}{(7 \text{ V})^2} = 0.061 \times 10^{-3} \text{ A/V}^2$$

Now

$$I_D = K (V_{GS} - V_{GS(th)})^2$$

In order to plot the transconductance curve for the device, we shall determine a few points for the curve by changing the value of $V_{GS}$ and noting the corresponding values of $I_D$.

- For $V_{GS} = 5 \text{ V} ; I_D = 0.061 \times 10^{-3} (5 \text{ V} - 3 \text{ V})^2 = 0.244 \text{ mA}$
- For $V_{GS} = 8 \text{ V} ; I_D = 0.061 \times 10^{-3} (8 \text{ V} - 3 \text{ V})^2 = 1.525 \text{ mA}$
- For $V_{GS} = 10 \text{ V} ; I_D = 0.061 \times 10^{-3} (10 \text{ V} - 3 \text{ V})^2 = 3 \text{ mA}$
- For $V_{GS} = 12 \text{ V} ; I_D = 0.061 \times 10^{-3} (12 \text{ V} - 3 \text{ V})^2 = 4.94 \text{ mA}$

Thus we can plot the transconductance curve for the E-MOSFET from these $V_{GS}/I_D$ points.

### 19.37 E-MOSFET Biasing Circuits

One of the problems with E-MOSFET is the fact that many of the biasing circuits used for JFETs and D-MOSFETs cannot be used with this device. For example, E-MOSFETs must have $V_{GS}$ greater than the threshold value ($V_{GS(th)}$) so that zero bias cannot be used. However, there are two popular methods for E-MOSFET biasing viz.

(i) **Drain-feedback bias**

(ii) **Voltage-divider bias**

(iii) **Drain-feedback bias.** This method of E-MOSFET bias is equivalent to collector-feedback bias in transistors. Fig. 19.59 (i) shows the drain-feedback bias circuit for $n$-channel E-MOSFET.
high resistance $R_G$ is connected between the drain and the gate. Since the gate resistance is superhigh, no current will flow in the gate circuit (i.e., $I_G = 0$). Therefore, there will be no voltage drop across $R_G$. Since there is no voltage drop across $R_G$, the gate will be at the same potential as the drain. This fact is illustrated in the d.c. equivalent circuit of drain-feedback bias as in Fig. 19.59 (ii).

\[ V_D = V_G \quad \text{and} \quad V_{DS} = V_{GS} \]

Since there is no voltage drop across $R_G$, the gate will be at the same potential as the drain. This fact is illustrated in the d.c. equivalent circuit of drain-feedback bias as in Fig. 19.59 (ii).

\[ \therefore \quad V_D = V_G \quad \text{and} \quad V_{DS} = V_{GS} \]

The value of drain-source voltage $V_{DS}$ for the drain-feedback circuit is

\[ V_{DS} = V_{DD} - I_D R_D \]

Since $V_{DS} = V_{GS}$, $V_{GS} = V_{DD} - I_D R_D$

Therefore, the $Q$-point of the circuit stands determined.

(ii) **Voltage-divider Bias.** Fig. 19.60 shows voltage divider biasing arrangement for $n$-channel E-MOSFET. Since $I_G = 0$, the analysis of the method is as follows:

\[ V_{GS} = \frac{V_{DD}}{R_1 + R_2} \times R_2 \]

and

\[ V_{DS} = V_{DD} - I_D R_D \]

where

\[ I_D = K (V_{GS} - V_{GS(th)})^2 \]

Once $I_D$ and $V_{DS}$ are known, all the remaining quantities of the circuit such as $V_D$, etc. can be determined.

**Example 19.36.** Determine $V_{GS}$ and $V_{DS}$ for the E-MOSFET circuit in Fig. 19.61. The data sheet for this particular MOSFET gives $I_{D(on)} = 500$ mA at $V_{GS} = 10V$ and $V_{GS(th)} = 1V$. 

**Solution.** Referring to the circuit shown in Fig. 19.61, we have,

\[ V_{GS} = \frac{V_{DD}}{R_1 + R_2} \times R_2 \]

\[ = \frac{24V}{(100 + 15) k\Omega} \times 15 k\Omega = 3.13V \]

The value of $K$ can be determined from the following equation:
Field Effect Transistors

\[
K = \frac{I_{D(on)}}{(V_{GS(on)} - V_{GS(th)})^2}
\]

\[
= \frac{500 \text{ mA}}{(10\text{ V} - 1\text{ V})^2} = 6.17 \text{ mA/V}^2 \quad \text{[Q \ V_{GS(on)} = 10\text{ V}]}
\]

\[
\therefore \quad I_D = K(V_{GS} - V_{GS(th)})^2 = 6.17 \text{ mA/V}^2 (3.13\text{ V} - 1\text{ V})^2 = 28 \text{ mA}
\]

\[
\therefore \quad V_{DS} = V_{DD} - I_D R_D = 24\text{ V} - (28 \text{ mA}) (470\Omega) = 10.8\text{ V}
\]

Example 19.37. Determine the values of \(I_D\) and \(V_{DS}\) for the circuit shown in Fig. 19.62. The data sheet for this particular MOSFET gives \(I_{D(on)} = 10\text{ mA}\) when \(V_{GS} = V_{DS}\).

\[\text{Fig. 19.62}\]

Solution. Since in the drain-feedback circuit \(V_{GS} = V_{DS}\),

\[
\therefore \quad I_D = I_{D(on)} = 10\text{ mA}
\]

The value of \(V_{DS}\) (and thus \(V_{GS}\)) is given by:

\[
V_{DS} = V_{DD} - I_D R_D
\]

\[
= 20\text{ V} - (10 \text{ mA})(1 \text{ k}\Omega) = 20\text{ V} - 10\text{ V} = 10\text{ V}
\]

Example 19.38. Determine the value of \(I_D\) for the circuit shown in Fig. 19.63. The data sheet for this particular MOSFET gives \(I_{D(on)} = 10\text{ mA}\) at \(V_{GS} = 10\text{ V}\) and \(V_{GS(th)} = 1.5\text{ V}\).

\[\text{Fig. 19.63}\]
Principles of Electronics

Solution. The value of \( K \) can be determined from the following equation:

\[
K = \frac{I_D(\text{on})}{(V_{GS(\text{on})} - V_{GS(\text{th})})^2}
\]

\[
= \frac{10 \text{ mA}}{(10 \text{ V} - 1.5\text{ V})^2} = 1.38 \times 10^{-1} \text{ mA/V}^2
\]

From the circuit, the source voltage is seen to be 0V. Therefore, \( V_{GS} = V_G - V_S = V_G - 0 = V_G \). The value of \( V_G (= V_{GS}) \) is given by:

\[
V_G (\text{or } V_{GS}) = \frac{V_{DD}}{R_1 + R_2} \times R_2 = \frac{10\text{ V}}{(1 + 1) \text{ M\Omega}} \times 1\text{ M\Omega} = 5\text{ V}
\]

\[
\therefore I_D = K (V_{GS} - V_{GS(\text{th})})^2
\]

\[
= (1.38 \times 10^{-1} \text{ mA/V}^2)(5\text{ V} - 1.5\text{ V})^2 = 1.69 \text{ mA}
\]

**MULTIPLE-CHOICE QUESTIONS**

1. A JFET has three terminals, namely .......
   (i) cathode, anode, grid
   (ii) emitter, base, collector
   (iii) source, gate, drain
   (iv) none of the above
2. A JFET is similar in operation to ...... valve.
   (i) diode      (ii) pentode
   (iii) triode   (iv) tetrode
3. A JFET is also called ...... transistor.
   (i) unipolar   (ii) bipolar
   (iii) unijunction (iv) none of the above
4. A JFET is a ...... driven device.
(i) current  
(ii) voltage  
(iii) both current and voltage  
(iv) none of the above  

5. The gate of a JFET is ...... biased.  
   (i) reverse  
   (ii) forward  
   (iii) reverse as well as forward  
   (iv) none of the above  

6. The input impedance of a JFET is ...... that of an ordinary transistor.  
   (i) equal to  
   (ii) less than  
   (iii) more than  
   (iv) none of the above  

7. In a p-channel JFET, the charge carriers are ......  
   (i) electrons  
   (ii) holes  
   (iii) both electrons and holes  
   (iv) none of the above  

8. When drain voltage equals the pinch-off voltage, then drain current ...... with the increase in drain voltage.  
   (i) decreases  
   (ii) increases  
   (iii) remains constant  
   (iv) none of the above  

9. If the reverse bias on the gate of a JFET is increased, then width of the conducting channel ......  
   (i) is decreased  
   (ii) is increased  
   (iii) remains the same  
   (iv) none of the above  

10. A MOSFET has ...... terminals.  
    (i) two  
    (ii) five  
    (iii) four  
    (iv) three  

11. A MOSFET can be operated with ......  
    (i) negative gate voltage only  
    (ii) positive gate voltage only  
    (iii) positive as well as negative gate voltage  
    (iv) none of the above  

12. A JFET has ...... power gain.  
    (i) small  
    (ii) very high  
    (iii) very small  
    (iv) none of the above  

13. The input control parameter of a JFET is ......  
    (i) gate voltage  
    (ii) source voltage  
    (iii) drain voltage  
    (iv) gate current  

14. A common base configuration of a pnp transistor is analogous to ...... of a JFET.  
    (i) common source configuration  
    (ii) common drain configuration  
    (iii) common gate configuration  
    (iv) none of the above  

15. A JFET has high input impedance because ......  
    (i) it is made of semiconductor material  
    (ii) input is reverse biased  
    (iii) of impurity atoms  
    (iv) none of the above  

16. In a JFET, when drain voltage is equal to pinch-off voltage, the depletion layers ......  
    (i) almost touch each other  
    (ii) have large gap  
    (iii) have moderate gap  
    (iv) none of the above  

17. In a JFET, $I_{DSS}$ is known as ............  
    (i) drain to source current  
    (ii) drain to source current with gate shorted  
    (iii) drain to source current with gate open  
    (iv) none of the above  

18. The two important advantages of a JFET are ............  
    (i) high input impedance and square-law property  
    (ii) inexpensive and high output impedance  
    (iii) low input impedance and high output impedance  
    (iv) none of the above  

19. ............ has the lowest noise-level.  
    (i) triode  
    (ii) ordinary transistor  
    (iii) tetrode  
    (iv) JFET  

20. A MOSFET is sometimes called ...... JFET.  
    (i) many gate  
    (ii) open gate  
    (iii) insulated gate  
    (iv) shorted gate  

21. Which of the following devices has the highest input impedance ?  
    (i) JFET
22. A MOSFET uses the electric field of a .......... to control the channel current.
(i) capacitor (ii) battery (iii) generator (iv) none of the above

23. The pinch-off voltage in a JFET is analogous to ......... voltage in a vacuum tube.
(i) anode (ii) cathode (iii) grid cut off (iv) none of the above

24. The formula for a.c. drain resistance of a JFET is ..............
(i) \( \frac{\Delta V_{DS}}{\Delta I_D} \) at constant \( V_{GS} \)
(ii) \( \frac{\Delta V_{GS}}{\Delta I_D} \) at constant \( V_{DS} \)
(iii) \( \frac{\Delta I_D}{\Delta V_{GS}} \) at constant \( V_{DS} \)
(iv) \( \frac{\Delta I_D}{\Delta V_{DS}} \) at constant \( V_{GS} \)

25. In class A operation, the input circuit of a JFET is .......... biased.
(i) forward (ii) reverse (iii) not (iv) none of the above

26. If the gate of a JFET is made less negative, the width of the conducting channel .......
(i) remains the same (ii) is decreased (iii) is increased (iv) none of the above

27. The pinch-off voltage of a JFET is about ...........
(i) 5 V (ii) 0.6 V (iii) 15 V (iv) 25 V

28. The input impedance of a MOSFET is of the order of ...............
(i) \( \Omega \) (ii) a few hundred \( \Omega \) (iii) k\( \Omega \) (iv) several M\( \Omega \)

29. The gate voltage in a JFET at which drain current becomes zero is called ............ voltage.
(i) saturation (ii) pinch-off (iii) active (iv) cut-off

30. The drain current \( I_D \) in a JFET is given by ..............
(i) \( I_D = I_{DSS} \left( 1 - \frac{V_{GS}}{V_P} \right)^2 \)
(ii) \( I_D = I_{DSS} \left( 1 + \frac{V_{GS}}{V_P} \right)^2 \)
(iii) \( I_D = I_{DSS} \left( 1 - \frac{V_{P}}{V_{GS}} \right)^2 \)
(iv) \( I_D = I_{DSS} \left( 1 + \frac{V_{P}}{V_{GS}} \right)^{3/2} \)

31. In a FET, there are .......... \( pn \) junctions at the sides.
(i) three (ii) four (iii) five (iv) two

32. The transconductance of a JFET ranges from ..............
(i) 100 to 500 mA/V (ii) 500 to 1000 mA/V (iii) 0.5 to 30 mA/V (iv) above 1000 mA/V

33. The source terminal of a JFET corresponds to .......... of a vacuum tube.
(i) plate (ii) cathode (iii) grid (iv) none of the above

34. The output characteristics of a JFET closely resemble the output characteristics of a .......... valve.
(i) pentode (ii) tetrode (iii) triode (iv) diode

35. If the cross-sectional area of the channel in \( n \)-channel JFET increases, the drain current ..............
(i) is increased (ii) is decreased (iii) remains the same (iv) none of the above

36. The channel of a JFET is between the .......... 
(i) gate and drain (ii) drain and source (iii) gate and source (iv) input and output

37. For \( V_{GS} = 0 \) V, the drain current becomes con-
40. At cut-off, the JFET channel is ............
(i) at its widest point
(ii) completely closed by the depletion region
(iii) extremely narrow
(iv) reverse biased

41. A MOSFET differs from a JFET mainly because ..............
(i) of power rating
(ii) the MOSFET has two gates
(iii) the JFET has a p-n junction
(iv) none of above

42. A certain D-MOSFET is biased at $V_{GS} = 0 \text{V}$. Its data sheet specifies $I_{DSS} = 20 \text{ mA}$ and $V_{GS(0f)} = -5 \text{V}$. The value of the drain current is ............
(i) 20 mA
(ii) 0 mA
(iii) 40 mA
(iv) 10 mA

43. An n-channel D-MOSFET with a positive $V_{GS}$ is operating in ..............
(i) the depletion-mode
(ii) the enhancement-mode
(iii) cut off
(iv) saturation

44. A certain p-channel E-MOSFET has a $V_{GS(0f)} = -2 \text{V}$. If $V_{GS} = 0 \text{V}$, the drain current is ............
(i) 0 mA
(ii) $I_{D(on)}$
(iii) maximum
(iv) $I_{DSS}$

45. In a common-source JFET amplifier, the output voltage is ............
(i) 180° out of phase with the input
(ii) in phase with the input
(iii) 90° out of phase with the input
(iv) taken at the source

46. In a certain common-source D-MOSFET amplifier, $V_{ds} = 3.2 \text{ V r.m.s.}$ and $V_{gs} = 280 \text{ mV r.m.s.}$ The voltage gain is ............
(i) 1
(ii) 11.4
(iii) 8.75
(iv) 3.2

47. In a certain CS JFET amplifier, $R_p = 1 \text{kΩ}$, $R_s = 560 \text{Ω}$, $V_{dd} = 10 \text{V}$ and $g_m = 4500 \text{ μS}$. If the source resistor is completely bypassed, the voltage gain is ............
(i) 450
(ii) 45
(iii) 2.52
(iv) 4.5

48. A certain common-source JFET has a voltage gain of 10. If the source bypass capacitor is removed, ............
(i) the voltage gain will increase
(ii) the transconductance will increase
(iii) the voltage gain will decrease
(iv) the Q-point will shift

49. A CS JFET amplifier has a load resistance of 10 kΩ and $R_p = 820 \text{Ω}$. If $g_m = 5 \text{ mS}$ and $V_m = 500 \text{ mV}$, the output signal voltage is ...
(i) 2.05 V
(ii) 25 V
(iii) 0.5 V
(iv) 1.89 V

50. If load resistance in Q. 49 is removed, the output voltage will ............
(i) increase
(ii) decrease
(iii) stay the same
(iv) be zero

Answers to Multiple-Choice Questions

| 1. (iii) | 2. (ii) | 3. (i) | 4. (ii) | 5. (i) |
| 6. (iii) | 7. (ii) | 8. (iii) | 9. (i) | 10. (iv) |
| 11. (iii) | 12. (ii) | 13. (i) | 14. (iii) | 15. (ii) |
| 16. (i) | 17. (ii) | 18. (i) | 19. (iv) | 20. (iii) |
| 21. (ii) | 22. (i) | 23. (iii) | 24. (i) | 25. (ii) |
| 26. (iii) | 27. (i) | 28. (iv) | 29. (ii) | 30. (i) |
| 31. (iv) | 32. (iii) | 33. (ii) | 34. (i) | 35. (i) |
| 36. (ii) | 37. (iii) | 38. (i) | 39. (iv) | 40. (ii) |
| 41. (iii) | 42. (i) | 43. (ii) | 44. (i) | 45. (i) |
| 46. (ii) | 47. (iv) | 48. (iii) | 49. (iv) | 50. (i) |
Chapter Review Topics

1. Explain the construction and working of a JFET.
2. What is the difference between a JFET and a bipolar transistor?
3. How will you determine the drain characteristics of JFET? What do they indicate?
4. Define the JFET parameters and establish the relationship between them.
5. Briefly describe some practical applications of JFET.
6. Explain the construction and working of MOSFET.
7. Write short notes on the following:
   (i) Advantages of JFET (ii) Difference between MOSFET and JFET

Problems

1. A JFET has a drain current of 5 mA. If \(I_{DSS} = 10 \text{ mA} \) and \(V_{GS(off)} = -6 \text{ V} \), find the value of (i) \(V_{GS}\) and (ii) \(V_P\).  
   \[ (i) -1.5 \text{ V} \] \[ (ii) 6 \text{ V} \]

2. A JFET has an \(I_{DSS}\) of 9 mA and a \(V_{GS(off)}\) of -3 V. Find the value of drain current when \(V_{GS} = -1.5\text{ V}\).  
   \[ 2.25 \text{ mA} \]

3. In the JFET circuit shown in Fig. 19.64 if \(I_D = 1.9 \text{ mA}\), find \(V_{GS}\) and \(V_{DS}\).  
   \[ -1.56 \text{ V}; 13.5 \text{ V} \]

4. For the JFET amplifier shown in Fig. 19.65, draw the d.c. load line.

\[ 	ext{Fig. 19.64} \] \[ 	ext{Fig. 19.65} \] \[ 	ext{Fig. 19.66} \]
5. For a JFET, $I_{DSS} = 9$ mA and $V_{GS} = -3.5$ V. Determine $I_D$ when (i) $V_{GS} = 0$ V (ii) $V_{GS} = -2$ V.
   
   $[\text{(i) 9 mA (ii) 1.65 mA}]$

6. Sketch the transfer curve for a $p$-channel JFET with $I_{DSS} = 4$ mA and $V_P = 3$ V.

7. In a D-MOSFET, determine $I_{DSS}$ given $I_D = 3$ mA, $V_{GS} = -2$ V and $V_{GS(off)} = -10$ V.
   
   $[4.69$ mA$]$;

8. Determine in which mode each D-MOSFET in Fig. 19.66 is biased.
   
   $[\text{(i) Depletion (ii) Enhancement (iii) Zero bias}]$

9. Determine $V_{DS}$ for each circuit in Fig. 19.67. Given $I_{DSS} = 8$ mA.
   
   $[\text{(i) 4V (ii) 5.4V (iii) -4.52V}]$

10. If a 50 mV r.m.s. input signal is applied to the amplifier in Fig. 19.68, what is the peak-to-peak output voltage? Given that $g_m = 5000 \mu$S.

   $[920$ mV$]$

**Discussion Questions**

1. Why is the input impedance of JFET more than that of the transistor?
2. What is the importance of JFET?
3. Why is JFET called unipolar transistor?
4. What is the basic difference between D-MOSFET and E-MOSFET?
5. What was the need to develop MOSFET?
